2. In a double-acting cylinder pump, the combination with the piston-cylinder and the outer casing, said cylinder being interiorly provided with longitudinal radial partitions dividing the casing into induction and suction chambers, transverse partitions closing the opposite ends of said chambers and dividing the upper and lower ends of said chambers respectively into auxiliary suction and induction chambers, two valve-enges connected together and removably fitted one above the other in the lower end of the piston-cylinder, the upper end of the lower cage being closed, and the lower end of the upper cage having a valve-opening, a ball seated to the upper end of the upper cage, reciprocating check-valves arranged in said cage, a piston in the piston-cylinder, parts connecting the auxiliary induction-chamber with the piston-cylinder above the closed end of the lower cage, parts connecting the piston-cylinder below said closed end of the lower cage with the induction-chamber, parts connecting the latter with the piston-cylinder above the piston, parts connecting the piston-cylinder above the valve-opening in the upper cage with the suction-chamber, and apertured check-valves controlling the discharge from the upper ends of the piston-cylinder and suction-chamber, substantially as described.

3. In a double-acting cylinder pump, the combination with the piston-cylinder and the outer casing, said cylinder being exteriorly provided with longitudinal radial partitions dividing the casing into induction and suction chambers, transverse partitions closing the opposite ends of said chambers and dividing the upper and lower ends of said chambers respectively into auxiliary suction and induction chambers, two valve-enges connected together and removably fitted one above the other in the lower end of the piston-cylinder, the upper end of the lower cage being closed and the lower end of the upper cage having a valve-opening, a ball seated to the upper end of the upper cage, centrally-perforated apertured check-valves arranged in said cage, guide-rods fixed in the cage and passing through said valves, a piston in the piston-cylinder, parts connecting the auxiliary induction-chamber with the piston-cylinder above the closed end of the lower cage, parts connecting the piston-cylinder below said closed end of the lower cage with the induction-chamber, parts connecting the latter with the piston-cylinder above the piston, parts connecting the piston-cylinder above the valve-opening in the upper cage with the suction-chamber, and apertured check-valves controlling the discharge from the upper ends of the piston-cylinder and suction-chamber, substantially as described.

4. In a double-acting cylinder pump, the combination with the piston-cylinder and the outer casing, said cylinder being provided with longitudinal radial partitions dividing the casing into induction and suction chambers, transverse partitions closing the opposite ends of said chambers and dividing the upper and lower ends of said chambers respectively into auxiliary suction and induction chambers, an impervious transverse partition in the lower portion of the piston-cylinder, an apertured partition above the impervious partition, a check-valve arranged in the lower end of the piston-cylinder and arranged to close its lower end, a check-valve arranged to seat on and close the apertured partition, a piston in the piston-cylinder, parts connecting the auxiliary induction-chamber with the piston-cylinder below, and transverse partitions, parts connecting the lower end of the piston-cylinder with the induction-chamber, parts connecting the latter with the piston-cylinder above the piston, parts connecting the piston-cylinder below the piston with the lower end of the suction-chamber, and apertured check-valves controlling the discharge from the upper ends of the piston-cylinder and suction-chamber, substantially as described.

698,888. ELECTRIC LAMP. JOHN ANDERSON and FRANK GUNN, New York, N. Y., assignors, by direct and mesne assignments, to Stanley Electric Manufacturing Company, a Corporation of New Jersey. Filed May 17, 1891. Serial No. 63,778. (No model.)

Claim.—1. An arc-lamp having the arc surrounded by a transparent or translucent substantially air-tight inclosure provided with an

apertured exit-passage free from obstructions to a natural flow of the gases, whereby a normal outflow of gases and maintained diffusion or exhaust with air is effected.

2. An arc-lamp having the arc surrounded by a transparent or translucent substantially air-tight inclosure, provided with an unrestricted passage leading to the atmosphere, said passage being of such diameter and length as will permit the normal outflow of gases without diffusion and prevent the ingress of the atmosphere.

3. An arc-lamp having the arc surrounded by a transparent or translucent substantially air-tight inclosure provided with an elongated passage leading from the interior of the inclosure to the atmosphere and free from obstructions to the natural flow of the gases and leading upward from the point of its connection with the inclosure and thence downward for the purpose set forth.

4. An arc-lamp having the arc surrounded by a transparent or translucent inclosure, a cover-plate for said inclosure, said cover-plate having an orifice for an electrode and another orifice for the escape of gases developed by the arc, and a bent tube connected to the second orifice and affording an unrestricted passage for the said gases.

5. An arc-lamp having the arc surrounded by a transparent or translucent substantially air-tight inclosure, a tube connecting directly with said inclosure affording free communication with the atmosphere and leading downward from its point of connection with the inclosure.

698,889. TUB BARK. CHARLES A. BARK, Chicago, Ill., assignor to Frederick E. Smith, Chicago, Ill. Filed May 9, 1891. Serial No. 63,671. (No model.)

Claim.—1. In a tub bark, in combination, a receptacle, a cover therefor, a carrier for delivering said tub to the receptacle, means for holding the cover, lock-extending means governed by the carrier, and means for holding the lock-extending means against movement when the carrier is retracted.

2. In a tub bark, in combination, a receptacle, a carrier for receiving a tub and depositing it in the receptacle, a rotatable catch-ring for holding the cover to the receptacle, a pawl mechanism for advancing the catch-ring and which is operated by a cam as conveyed by the carrier-plate, and a stop on the carrier-plate for holding the pawl mechanism against movement when the carrier-plate is retracted.

3. In a tub bark, in combination, a receptacle, a cover therefor, a carrier-plate for receiving a tub and depositing it in the receptacle, a rotatable catch-ring for holding the cover to the receptacle, a pawl for advancing the catch-ring, a lever to which the pawl is connected, a cam

on the lever and which is engaged by a cam as conveyed by the carrier-plate in either direction, and a stop, the said lever having an arm which engages the stop to prevent backward movement of the lever.

4. In a tub bark, in combination, a receptacle having an internal annular flange provided with a slot, a non-rotatable cover for the receptacle, a catch-ring carried by the cover and having a projection engaging the flange to lock the cover to the receptacle, a cam-carrier representing across the cover and within the space bounded by the catch-ring and for receiving a cam and depositing it in the receptacle, a pawl engaging the catch-ring, and a lever extending the pawl, the movement of the lever being governed by the cam as conveyed by the cam-carrier.

5. In a tub bark, in combination, a receptacle, a cover, a carrier-plate for receiving a tub and depositing it in the receptacle, a rotatable catch-ring mounted to the cover and having means for locking the cover to the receptacle, a lever, a pawl carried by the lever for rotating the catch-ring, the lever having a cam which is engaged by a cam as conveyed by the carrier-plate for unlocking the cover, and a stop for preventing movement of the lever when the carrier-plate is in its retracted position.

6. In a tub bark, in combination, a receptacle, a cover therefor comprising two members spaced apart and provided with non-engaging cam-apertures, a rotatable catch-ring carried by one of said cover members and having projections engaging the flange to lock the cover to the receptacle, a cam-carrier having a pocket and which represents between the cover members and within the space bounded by the catch-ring, a pawl engaging the catch-ring, a pivoted lever to which the pawl is connected, and a cam projecting from the lever and into the path of the cam carried in the pocket of the cam-carrier.

7. In a tub bark, in combination, a receptacle, a cover therefor comprising two members spaced apart and provided with non-engaging cam-apertures, a rotatable catch-ring carried by one of said cover members and having projections engaging the flange to lock the cover to the receptacle, a carrier-plate having a pocket and carried by the cover member carrying the catch-ring, the said carrier-plate representing between the cover members and within the catch-ring, a pawl engaging the catch-ring, a lever pivoted to the cover member carrying the catch-ring and between the latter and the carrier-plate, a spring-pawl secured to the lever for actuating the catch-ring, and a cam projecting from the lever and into the path of the cam carried in the pocket of the carrier-plate.

698,890. FOLD-UP REINFORCED FOR VEHICLES. THOMAS H. BARK, London, England, assignor of seven-tenths to Charles William Walker, Bradford, Yorkshire, England. Filed July 12, 1891. Serial No. 64,081. (No model.)

Claim.—1. The combination with a carriage-pole of a backing arm or arms supported by the pole and projecting forward of the animal's collar considerably beyond the plane of the animal's normal draft position and formed with clip-hook ends curving to enable the animal's collar-rings to be easily yoked to and unyoked from the arms and to provide for a wide extent of free travel of the collar-rings along the arms on each side of the animal's normal draft position, so as to enable the animal to run straight and parallel and to cause their wandering or backing action on the vehicle to be effected in places parallel to the pole at whatever distance therefrom they may happen to be when pulled up, as set forth.

2. The combination with a vehicle-pole, of an arm curving as a backing attachment, and a collar-connecting device, the arm being connected to the pole and extending considerably beyond the plane of the animal's normal draft position, and the connecting device having unrestricted free play along the arm to the extent of the animal's liberty of lateral movement on each side of its normal position, so enabling the animal to run straight and parallel with the pole and to cause its backing action on the vehicle to be effected in places parallel with the pole at whatever distance therefrom it may happen to be when pulled up, as set forth.

3. The combination with a vehicle-pole, of an arm connected thereto and extending considerably beyond the plane of the animal's normal draft position, a collar-connecting ring on said arm having unrestricted free play along the arm to the extent of the animal's liberty of lateral movement on each side of its normal position, and a clip-hook at the end of the arm, whereby the animal can be readily yoked and unyoked, as

run straight and parallel with the pole and exert its locking action on the vehicle in a plane parallel with the pole at whatever distance therefrom it may happen to be when pulled up.

698,891. WIND-WHEEL. BENJAMIN GARDNER, Pittsburg, Tex. Filed May 21, 1901. Serial No. 68,698. (No model.)

Claim.—1. A wind-wheel, having the centrally-pivoted fan, the eccentric wheel engaging said fan, and the belt connection for the fan pivots or shafts, substantially as specified.

2. A wind-wheel, having the opposite shafts, the eccentric wheel being in crank-bearing in said shaft, the fan-shaft journaled in the peripheral portion of said shaft, and arranged to bear upon the rim of said eccentric wheel, and means for turning said wind-wheel to one side to prevent the fan from or less edgewise to the wind under variations in the force thereof, substantially as specified.

3. In a wind-wheel, the combination with the pivoted fan, the eccentric wheel upon which said fan bears, and the endless belt connecting the shafts of said fan, of means opening in connection with said eccentric wheel and belt for exerting a pull upon said belt at intervals to draw the fan past radial position, substantially as specified.

4. In a wind-wheel, the combination with the pivoted fan, the eccentric wheel, and the sprocket-chain connecting the shafts of said fan, of means carried by said fan, and arranged to take a bearing upon the rim of said eccentric wheel to exert a pull upon said chain at intervals to draw the fan past radial position, substantially as specified.

5. The combination with a wind-wheel having the supporting-frame turning upon a vertical axis, of a vane turning upon the same axis as said frame, the pole of fan pivoted to said vane, the knee or toggle joint connecting said fan, one of said fan having a connection with said vane, and the other said fan having a rope or cable attachment, upon which a weight is suspended, substantially as specified.

698,892. ALARM. ARTHUR R. GOWAN, Richmond, Va., assignor of one-half to HERBERT A. ROSS, Richmond, Va. Filed Nov. 20, 1901. Serial No. 84,194. (No model.)

Claim.—1. In a bell-alarm, the combination of a rotatably-supported bell provided with striking parts, a hammer supported on an elastic arm, a motor-spring for rotating the bell, a detent engaging in a notch in the bell to hold it when wound up, means for holding the detent in the notch, and means for throwing the detent out of the notch to release the bell when the means for holding the detent in engagement with the notch is removed.

2. In a bell-alarm, the combination of a rotatably-supported bell provided with striking parts, means for rotating the bell, an elastically-supported hammer, an arm 6 provided with a detent and 9 engaging the bell to hold it when wound up, a cap 14 to hold the detent 9 in engagement with the bell, and a spring 16 arranged to throw the detent 9 out of engagement with and so release the bell when the cap 14 is removed.

3. In a bell-alarm, the combination of a base-plate, a bell-post, a bell rotatably mounted on the bell-post and provided with striking parts, an elastically-mounted hammer lying in the path of the said striking parts, a spring 12 fixed at one end and 13 attached by its other end to the bell that when it is wound up it will revolve the bell, an arm 8 pivoted to the base-plate and terminating at one end in a detent 9 adapted to engage in a notch in the edge of the bell, removable means for keeping the arm in position, and a spring 16 arranged to throw the detent out of engagement with and so release the bell when the means for keeping the arm in position is removed.

4. In a bell-alarm, the combination of a base-plate, a bell-post, a bell rotatably mounted on the bell-post and provided with striking parts, an elastically-mounted hammer lying in the path of the said striking parts, a spring 12 fixed at one end and 13 attached by its other end to the bell that when it is wound up it will revolve the bell, an arm 8 pivoted to the base-plate and terminating at one end in a detent 9 adapted to engage in a notch in the edge of the bell, removable means for keeping the arm in position, a spring 16 arranged to throw the detent out of engagement with and so release the bell when the means for keeping the arm in position is removed, and a spring 11 to hold the bell in engagement with the detent 9 when the alarm is set.

5. In a bell-alarm, the combination of a rotatably-supported bell provided with projecting striking parts, a hammer adapted to come in contact with the said striking parts as the bell revolves, means for rotating the bell, means for holding the bell, and means for releasing the bell.

698,893. CLOTHES-LINE PINS. WILSON & BAYNE, Chicago, Ill. Filed Feb. 1, 1901. Serial No. 84,195. (No model.)

Claim.—1. In an extension clothes-pin, the combination, with the extension members having means for holding them in sliding engagement with each other, of a vibratory yoke connected with the lower pole member and embracing the upper pole member and a clamp-block movably mounted on the free end of the yoke and arranged to engage the sliding pole member by downward inclination of said yoke.

2. In an extension clothes-pin, the combination, with the extension-pole members provided with means for holding them in sliding engagement with each other, of a spring-yoke carried by the lower pole member and embracing the upper pole member, and a clamp-block carried pivotally by the yoke at its free end and engaging with the upper pole member, said spring-yoke normally having a slight downward inclination toward the clamp-block, substantially as set forth.

3. In an extension clothes-pin, the combination, with the extension-pole members provided with means for holding them in sliding engagement with each other, of a spring-yoke metal yoke having an end of the wire bent inward and entering the lower pole member to give rigid attachment of the yoke thereto, a clamp-block carried pivotally by the yoke at its free end and engaging the outer face of the upper pole member, said rigidly-attached spring-yoke having a slight downward inclination from the point of its attachment whereby the clamp-block is normally pressed against the upper pole member, substantially as described.

698,894. INSULATED-LAMP SOCKET. LAWRENCE P. BROWN, Toledo, Ohio, assignor to THE MILLER COMPANY, Toledo, Ohio. Filed May 6, 1901. Serial No. 84,201. (No model.)

Claim.—1. In an insulated-lamp socket, the combination of an insulating-socket compound of two connecting parts or sections provided in their meeting edges with recesses forming sockets, switch mechanism,

bearing-plates removably mounted in said sockets in the casing and formed with apertures, and confined by the connecting of the parts of the casing together, and a key-spindle projecting through the apertures in the bearing-plates and adapted to turn therein, said spindle being provided at one end with a stop holding it against endwise movement in one direction and at the other end with a key-handle holding it against endwise movement in the reverse direction, substantially as described.

2. In an insulated-lamp socket, the combination of an insulating barrel or casing comprising sections, sections removably mounted in said sockets and confined by the sections of the casing and provided with openings, and a key-spindle coacting with said switch mechanism and extending through the openings in the bearing-plates, said spindle being provided with end stops to retain the bearing-plates thereon and to hold the spindle against independent endwise movement, one of said stops being formed by bending or splicing one of the ends of the spindle, whereby, when said barrel end is bent back to its normal position, the bearing-plates may be slid endwise off the spindle, substantially as described.

3. In an insulated-lamp socket, the combination with an insulating barrel or casing composed of sections, conducting-plates connecting said sections, lamp-contacts, a bearing-plate formed upon one of the said conducting-plates, a pivot-pin connected to said bearing-plate and provided at its free end with a head, a half-switch pivotally mounted upon said pin and provided at its free end with a contact-piece adapted to engage the contact-piece on the other part of the circuit, a spring surrounding said pivot-pin between the head thereof and the switch and acting to hold the switch pressed into contact with the bearing-plate, said spring also being connected with the switch to throw it open, and means for operating the switch, substantially as described.

4. The combination, in a switch or circuit-breaker, of a conductor, a contact-piece, a pivot-pin, a half-switch slidably and pivotally mounted upon said pin and in normal engagement with the conductor and adapted to be swung into and out of engagement with the contact-piece to make and break the circuit, said switch comprising a plate having a body portion and end portions extending at right angles thereto, one forming a pivot-piece and the other a contact-piece, a shoulder being formed by the end of the body adjacent to said pivot-piece, a spring surrounding the pivot-pin and secured at one end and acting upon the pivoted end of the switch to press it into engagement with the conductor, the opposite end of the spring being arranged to bear against said shoulder to throw the switch open, and means for operating the switch, substantially as described.

5. In an insulated-lamp socket, the combination of an insulating barrel or casing composed of sections, the base of the lower section being formed in its upper surface with recesses opening through the edges thereof and disposed upon opposite sides of the center of said base diagonally with relation to each other, and also with a central recess, conducting-plates having right-angularly-bent ends, the lower right-angularly-bent ends being fitted in said side recesses or sockets, fastenings connecting the said right-angularly-bent ends of the conducting-plates to the top and bottom sections of the casing, binding-posts carried by said conducting-plates for attachment of lamp-wires, a lamp-socket secured by the fastening means of the lower right-angularly-bent end of one of the said conducting-plates, a contact-plate fitted in the central recess of the bottom section of the casing and carrying a contact-piece, a fastening device securing said plate to the base-casing section, a second lamp-socket secured to the casing by said latter-mentioned fastening device, a bearing-plate carried by one of said conducting-plates, a pivot-pin connected thereto and provided with a head, a half-switch pivotally mounted upon said pin and adapted to bear against said bearing-plate and to be thrown into and out of engagement with the contact-piece carried by the said central contact-plate, a spring surrounding said pivot-pin and fixed at one end and arranged to press the switch against the bearing-plate, and having its opposite end connected with the switch to throw the same open, and means for operating said switch, substantially as described.

6. The sections 5 and 6, formed with central chambers for the reception of the switch mechanism, and adapted to be connected together to form a continuous insulating-casing, and also provided with diametrically-disposed recesses or pockets having intersecting spindle-channels, and adapted to receive spindle-supporting disks or plates, substantially as set forth for the purpose set forth.

7. In an insulated-lamp socket, the combination of an insulating-casing adapted to receive the switch mechanism and conducting-plates and their connections, the switch pivotally connected at one end with one of the conducting-plates and having its free end of U shape, a contact-plate having one end V-shaped to receive the U-shaped end of the operating switch, a switch-operating spindle and tumbler, and spring mechanism for restoring the switch to its normal position, substantially as set forth.

698,895. SUPPORT FOR PUNCHING-SAWS. GARY W. DUGLEY, Chicago, Ill. Filed Feb. 1, 1901. Serial No. 84,196. (No model.)

Claim.—The combination of a supporting-rod, a cap-shaped hollow body made of a single piece of sheet metal and provided at its upper edge with a flat, horizontal, outwardly-directed, integral attaching-flange and in its bottom with an upwardly-directed, integral, conical flange which forms a vertical, tubular passage for the rope not materially larger than said rope, and the base of which flange outwardly to its line of junction with the bottom of the cap-shaped body, a flat, centrally-located bearing-plate located within the said hollow body and resting on the upwardly-directed edge of said flange, said cord extending upwardly through the passage formed thereby in the bottom of the cap-shaped body and through the bearing-plate and having at its upper end a knot which engages the top surface of said bearing-plate, and said hollow body having an opening in its side wall above said bearing-plate to afford access to said knot.

698,896. FOLDING UMBRELLA. JOHN A. BROWN, Minneapolis, Minn., assignor of one-fourth to ROSE A. JOHNSON, Hartford, Conn. Filed Feb. 26, 1901. Serial No. 84,207. (No model.)

Claim.—In a folding umbrella, a rod composed of three jointed sections, each having an end reduced to slip in the end of the adjacent section, short coupling-sections interior of the other sections opposite the joints, a pair of sleeves slidably mounted upon the sections one above the other, the upper one when it is raised being adjacent the joint of the upper and central sections, a wire spring-clip located in the lower section to engage the lower sleeve to hold the same down when the umbrella is closed, another wire spring-clip in the central section to hold the sleeve up when the umbrella is raised, a hooked spring provided with a leg mounted in the middle section to hold one of the couplings in place, and another similar spring mounted in the upper section to hold the upper sleeve in place.

698,897. FOLDING BUTTER LUGGAGE-SKID. JOHN A. BROWN, Minneapolis, Minn., assignor of one-fourth to ROSE A. JOHNSON, Hartford, Conn. Filed Feb. 26, 1901. Serial No. 84,208. (No model.)

Claim.—1. In a folding or collapsible box consisting of a jointed metal frame having clamping-lugs pivotally attached thereto, the sides, ends and bottom of the box formed from cloth or other flexible material, ends or lugs for attaching the sides, ends and bottom to the frame, an L-shaped hook rigidly attached to said frame, and means for removably attaching the box to a bicycle consisting of a clamp having a forward extension, and an L-shaped recess in said extension to receive the hook, substantially as described.

2. In combination a folding box, a top frame consisting of a centrally-hinged front member, side members hinged to the ends of the front member, and hinged intermediate of their lengths, and a centrally-hinged rear member having the side hinged to its ends, a flexible box connected to the frame, a flanged plate embracing said central portion of the rear member of the frame, an L-shaped hook carried by said plate, a spring-catch carried by said plate and means for connecting the box to a bicycle-frame detachably engaging the hook and held in rigid engagement by the spring-catch.

3. In combination a folding box, a top frame consisting of a centrally-hinged front member, side members hinged to the ends of the front member, and hinged intermediate of their lengths, and a centrally-hinged rear member having the side hinged to its ends, a flexible box connected to the frame, a flanged plate embracing said central portion of the rear member of the frame, an L-shaped hook carried by said plate, consisting of a clamp having a forward extension and an L-shaped recess in said extension to receive the hook.

698,898. APPARATUS FOR SEPARATING SOLVENTS FROM OIL. CLARENCE BURNHAM, DORCHESTER, MASS., assignor to Frank H. Pratt, Dorchester, Mass. Filed Aug. 21, 1901. Serial No. 72,988. (No model.)

Claim.—1. An apparatus for separating oil from an oil-containing solvent, comprising a closed chamber, a vertical pipe in the chamber forming a passage-way for a heating medium, and means for supplying the

combined oil and solvent in a thin film around the outside of the upper part of the pipe.

2. An apparatus for separating oil from an oil-containing solvent, comprising a closed chamber, a coil of pipe disposed vertically in the chamber and forming a passage-way for a heating medium, and means for supplying the combined oil and solvent in a thin film around the outside of the upper part of the pipe.

698,899. METHOD OF MAKING MAGNESIUM-PEROXIDE COMPOUND. FRANK FURBER, Berlin, Germany. Filed Jan. 7, 1902. Serial No. 66,786. (No specimens.)

Claim.—1. The process herein described of producing a compound rich in magnesium peroxide, which consists in forming an aqueous mixture of a soluble salt, a corresponding ammonium salt and sodium peroxide, adding to the mass, after the resulting reaction, a quantity of alcohol, and separating the precipitate from the liquid, substantially as set forth.

2. The process herein described of producing a compound rich in magnesium peroxide, which consists in forming an aqueous mixture of magnesium chloride, ammonium chloride and sodium peroxide, adding to the mass, after the resulting reaction, a quantity of alcohol, and then separating the precipitate from the liquid, substantially as set forth.

3. The process herein described of producing a compound rich in magnesium peroxide, which consists in dissolving in water a soluble magnesium salt, allowing the solution to cool, adding gradually to the solution a mixture of the corresponding ammonium salt and sodium peroxide, allowing the mixture to stand, separating the precipitate from the liquid, drying the precipitate at a low temperature, substantially as set forth.

4. The process herein described of producing a compound rich in magnesium peroxide, which consists in dissolving in water a soluble magnesium salt, allowing the solution to cool, adding gradually to the solution a mixture of the corresponding ammonium salt and sodium peroxide, adding to the mass, after the resulting reaction, a quantity of alcohol, allowing the mixture to stand, separating the precipitate from the liquid, drying the precipitate at a low temperature, substantially as set forth.

5. The process herein described of producing a compound rich in magnesium peroxide, which consists in dissolving in water a soluble magnesium salt, allowing the solution to cool, adding gradually to the solution a mixture of the corresponding ammonium salt and sodium peroxide, adding to the mass, after the resulting reaction, a quantity of alcohol, drying the mixture to stand, separating the precipitate from the liquid, drying the precipitate at a low temperature, grinding the precipitate, mixing the same with water, filtering and washing the product, and repeatedly drying and pulverizing the mass, substantially as set forth.

698,400. VACUUM-PUMP. WILLIAM F. GARDNER, Brooklyn, N.Y., assignor to Smith & Garrison, Brooklyn, N.Y., a firm. Filed Aug. 1, 1901. Serial No. 76,664. (No model.)

Claim.—1. In a vacuum-pump, two chambers communicating respectively one with each end of the cylinder, an inlet-chamber and a discharge-chamber each common to both ends of the cylinder, and oppositely-located valve-containing diaphragms situated one between one of said two chambers and the inlet and outlet chambers and the other between the other of said chambers and the inlet and outlet chambers, substantially as herein described.

2. In a vacuum-pump, two chambers communicating respectively one with each end of the cylinder, an inlet-chamber and a discharge-chamber each common to both ends of the cylinder and two valve-containing diaphragms situated one between one of said two chambers and the inlet and outlet chambers and the other between the other of said two chambers and the inlet and outlet chambers, said diaphragms having induction communicating respectively at the middle of the length of the cylinder and running outwardly therefrom in opposite directions, substantially as herein described.

3. In a vacuum-pump, a valve-chest in which are two chambers communicating respectively one with each end of the cylinder, a discharge-chamber common to both of said two chambers, and two valve-containing diaphragms arranged one between said discharge-chamber and one of the two first-mentioned chambers and the other between said discharge-chamber and the other of said first-mentioned chambers and having induction in opposite directions, substantially as herein described.

4. In a vacuum-pump, a valve-chest in which are two chambers communicating respectively one with each end of the cylinder, an inlet-chamber common to both of said two chambers, a discharge-chamber common to both of said two chambers, and two oppositely-located valve-containing diaphragms one of said diaphragms separating one of said two chambers from both the inlet and discharge chambers and the other of said diaphragms separating the other of said two chambers from both the inlet and discharge chambers, substantially as herein described.

698,401. GOLF-BALL. BRADLEY KIRKMAN, Boston, Mass., assignor to the Knapton Manufacturing Company, a Corporation of New Jersey. Filed Mar. 24, 1902. Serial No. 66,715. (No model.)

Claim.—1. A playing-ball comprising a yielding core and a substantial, continuous shell holding said core under compression, and consisting of gutta-percha from which all strains other than those caused by the expansive tendency of said core have been eliminated.

2. A playing-ball comprising a core and a shell thereof, the latter consisting of convolutions of one or more strips of plastic material extending continuously in different directions around said core and being welded together or adhering at their contacting surfaces.

3. A playing-ball comprising a core and a shell thereof, the latter consisting of convolutions of one or more strips of gutta-percha extending continuously in different directions around said core and being welded together at their contacting surfaces.

4. A playing-ball comprising a shell and a yielding core held under compression thereby; said shell consisting of convolutions of one or more strips of gutta-percha extending continuously in different directions around said core and being welded together at their contacting surfaces.

5. A playing-ball comprising a core and a shell thereof, the latter consisting of convolutions of one or more strips of gutta-percha extending continuously in different directions around said core and being welded together at their contacting surfaces; the internal strains of said shell being substantially eliminated.

698,402. GOLF-BALL. BRADLEY KIRKMAN, Boston, Mass., assignor to the Knapton Manufacturing Company, a Corporation of New Jersey. Filed Mar. 21, 1902. Serial No. 102,731. (No model.)

Claim.—1. A playing-ball comprising a core which consists mainly of wide, solid rubber bands wound thereon under tension, and a shell of plastic material upon said core, said shell being lined with fabric.

2. A playing-ball comprising a core which consists mainly of wide, solid rubber bands wound thereon under tension, and a gutta-percha shell upon said core, said shell being lined with fabric.

3. In a playing-ball, the combination of a center plate; with solid rubber bands wound thereon therefrom to form the main part of a core, and a gutta-percha shell holding said core under compression.

4. In a playing-ball, the combination of a center plate; with solid rubber bands wound thereon therefrom to form the main part of a core, and a gutta-percha shell compressed upon said core and provided with a fabric lining.

5. A playing-ball comprising a core and a shell; the said core being formed mainly of wide, solid, thin rubber bands wound thereon under

high tension, and said shell being formed of plastic material lined with fabric and confining said core in reduced bulk.

698,403. STEAM-GENERATOR. CHARLES A. KIRBY, Oswego, N.Y.; Morris W. Kline, administrator of said Charles A. Kirby, deceased, assignor to Steam Carriage Oil Company, Oswego, N.Y., a Corporation of New York. Filed June 3, 1901. Serial No. 65,686. (No model.)

Claim.—1. A steam-generator comprising oppositely-arranged sections having their adjacent edges welded to each other, and a diaphragm loosely supported between the end walls of said sections, at one side of the meeting ends of the sections.

2. A steam-generator comprising oppositely-arranged shells having adjacent ends open and welded to each other and their opposite ends provided with perforated heads, a perforated diaphragm loosely supported in one of the heads at one side of their welded ends and capable of movement independently of the shell, and flues inserted through the apertures of the heads and diaphragm and secured to the heads.

3. A steam-boller having oppositely-perforated heads, in combination with a perforated diaphragm loosely mounted in the boiler and capable of independent rotary motion, means projecting from the sides of the boiler to support the diaphragm and flues inserted through the heads and diaphragm and secured to the heads.

4. A steam-boller having oppositely-perforated heads and studs projecting inwardly from its side walls, in combination with a perforated diaphragm having elongated slots receiving the studs for supporting the diaphragm and permitting the diaphragm to be partially rotated independently of the boiler-shell.

5. A steam-boller comprising oppositely shell-sections having adjacent ends open and welded to each other and provided with perforated heads and studs projecting inwardly from its side walls, a perforated diaphragm within the boiler having an outer flange provided with elongated slots receiving said studs for permitting partial rotation of the diaphragm independently of the boiler-shell.

698,404. MACHINE FOR BULGING SHEET-METAL VESSELS. GEORGE W. KRAFT, Baltimore, Md., assignor to National Bulging & Shaping Co., a Corporation of New Jersey. Filed Apr. 12, 1901. Serial No. 58,668. (No model.)

Claim.—1. In a machine for bulging the sides of sheet-metal vessels having bottoms, the combination of a bed-plate for the vessel to rest on while it is being expanded; a plurality of radial blades all of which together form a substantially circular expandable part with an opening at the center and the outer wall of each blade being curved in the direction of its upper and lower ends; a plate by which said blades are supported

and on which they have a radially-sliding movement, and on which they are carried into and out of the vessel that is to be bulged; a vertically-reciprocating cross-head; and a tapered plug carried by said cross-head and moved in the said central opening of the radial blocks.

2. In a machine for bulging the sides of sheet-metal vessels having bottoms, the combination of a vertically-reciprocating cross-head; a tapered plug rigidly attached to said cross-head; a plurality of radial blocks all of which together form a substantially circular expandable part with a central opening which receives the said tapered plug, all of said blocks being loosely expanded and having a limited up-and-down movement relative to said tapered plug and the outer wall of each block being convex in the direction of its upper and lower ends; a plate by which said blocks are supported and on which they have a radially-sliding movement; and a stationary bed-plate below all of the abovedescribed parts and on which the sheet-metal vessel will rest while the expansion of the radial blocks takes place.

3. In a machine for changing the straight, cylindrical shape of the sides of sheet-metal vessels, such as cans, pots, and analogous vessels, into expanded or bulged shape, the combination of a vertically-reciprocating cross-head; a tapered plug carried by said cross-head; a plurality of radial blocks independent of each other and all of which together form a substantially circular expandable part with a central opening which receives the said tapered plug, the said blocks and said plug having an independent limited up-and-down movement with respect to each other and said blocks also having a radially-sliding movement; a plate by which said blocks are supported and carried into and out of the vessel that is to be expanded; and a bed-plate below all of the abovedescribed parts and on which the sheet-metal vessel will rest while the expansion of the radial blocks takes place.

4. In a machine for bulging the sides of sheet-metal vessels having bottoms, an expanding-die comprising a plurality of radial blocks which together form the circle of the expanding-die and each block provided with an inner inclined wall all of which walls together form an opening in the center of the die, and the outer wall of each block being convex in the direction of its upper and lower ends; a plate adapted to sit within the sheet-metal vessel and rest on the bottom thereof and support the said radial blocks; and a tapered plug in the center opening of the die and in contact with the inner inclined walls of all the blocks, whereby the straight, cylindrical sides of the vessel may be changed to bulged sides without using an exterior die or former.

5. In a machine for bulging the sides of seamless sheet-metal vessels having bottoms, an expanding-die comprising a plurality of radial blocks which together form the circle of the expanding-die with an opening at the center and said blocks provided at their top and bottom with annular channels; compression-springs in said channels and tending to press said radial blocks together; a bed-plate on which the bottom of the sheet-metal vessel may rest while the vessel is being expanded; a plate adapted to sit within the sheet-metal vessel and rest on the bottom thereof and support the said radial blocks so that the latter may slide radially on said plate; and a tapered plug in the center opening of the die and adapted to press said radial blocks apart.

6. In a machine for bulging the sides of sheet-metal vessels having bottoms, the combination of a vertically-reciprocating cross-head provided with a socket; a tapered plug rigidly attached to and depending from said cross-head, and provided with a vertical bore opening into said socket; a pin mounted to slide in said bore with its upper end extending into said socket and provided with a head adapted to limit the downward movement of said pin in said bore; a plate secured to the lower end of said pin; and a plurality of radial blocks supported by and slidable on said plate and grouped around said pin and provided with inner inclined walls engaged by said pin and said blocks also provided with outer walls uniformly convex from top to bottom.

7. In a machine for bulging the sides of sheet-metal vessels having bottoms, the combination of a vertically-reciprocating cross-head provided with a socket; a tapered plug rigidly attached to and depending from said cross-head and provided with a vertical bore opening into said socket; a pin mounted to slide in said bore with its upper end extending into said socket and provided with a head adapted to limit the downward movement of said pin in said bore; a plate rigidly secured to the lower end of said pin; a plurality of radial blocks supported to slide on said plate and grouped around said pin, and provided with inner inclined walls engaged by said pin; and compression-springs acting on the top and also on the bottoms of said radial blocks to press the said blocks together, as set forth.

8. In a machine for bulging the sides of sheet-metal vessels having bottoms, the combination of a vertically-reciprocating cross-head; a tapered plug rigidly attached to said cross-head; a plurality of radial blocks independent of each other and all of which together form an expandable part with a central opening which receives the said tapered plug—each block being provided at its top and also at its bottom with a recess all of

which together form annular channels at the top and bottom of the said expandable part; an endless spiral spring in each of said channels and tending to press said radial blocks together; and a bed-plate on which the bottom of the sheet-metal vessel may rest while the vessel is being expanded.

9. In a machine for bulging the sides of sheet-metal vessels such as cans, pots, and analogous vessels, the combination of a plurality of die-blocks all of which together form a substantially circular expandable part with an opening at the center; a reciprocable support from which said die-blocks are expanded and with respect to which blocks said support has an independent limited up-and-down movement; a plate in contact with the lower ends of all the expanding die-blocks; and a tapered plug movable in the center opening of said die-blocks.

698,408. SPEED-REGULATOR FOR EXPLOSIVE-ENGINE.
JOHN W. LARKIN, Anderson, Ind., assignor to the Bushy Manufacturing Company, Anderson, Ind. Filed June 27, 1901. Serial No. 64,382. (No model.)

Claim.—1. The combination with a gas-engine, of a cam and means for rotating it from the engine-shaft, this cam having sparking and exhaust-enlargements respectively at opposite sides, an exhaust-valve and a two-part inlet for said valve, means for normally closing the valve, an actuation device carried by one part of said inlet and adapted to bear upon said cam and be operated thereby, igniter mechanism, and a trip-rod adapted to operate the cam, said trip-rod being connected to the part of the valve-rod carrying the actuation device, for the purpose set forth.

2. In combination with a gas-engine, a cam adapted to receive rotation therefrom and to act both as a sparking and an exhaust cam having sparking and exhaust-enlargements respectively at opposite sides, the sparking enlargement being lower than the exhaust enlargement, an exhaust-valve having a two-part rod, one part being connected directly to the valve and the other part being adapted to be operated by said cam, igniter device, and means for operating them by connection directly with the cam-operated part of the valve-rod, for the purpose set forth.

3. In combination with a gas-engine, a cam adapted to receive both as a sparking and an exhaust cam, having sparking and exhaust-enlargements respectively at opposite sides, means for rotating this cam from the engine, an exhaust-valve having a two-part stem, one part being connected directly to the valve and the other part being operated directly by the cam, igniter mechanism and means for operating it by connection with the cam-operated part of the valve-rod, and speed-regulating device constructed and arranged to hold the cam-operated part of the valve-rod out of engagement with the cam, the exhaust-valve off its seat and the igniter mechanism out of operation upon abnormal speed.

4. In combination with a gas-engine, an igniter mechanism consisting of a stationary electrode, a movable electrode consisting of a rod

shank, extending into the sparking-chamber and provided with a movable contact-arm, an arm rigidly attached to said shank on its outer end, a loose arm mounted on said shank adjacent to the rigid arm, a spring bearing against said rigid arm and normally holding the contacts apart, a spring between said two arms, a stop device engaging the loose arm, and a trip-rod adapted to engage the loose arm and force it toward the rigid arm and thereby bring the contacts together, and means for disengaging said trip-rod from said loose arm.

698,408. MATCH-SAFE. SYLVANUS B. LOCKE, Bridgeport, Conn., assignor of one-half to Martin McVey, Jr., New York, N. Y. Filed Apr. 14, 1901. Serial No. 64,644. (No model.)

Claim.—1. A match-safe comprising a casing, a reservoir for the matches, a drop arranged to tilt a match into position to be withdrawn from the safe, a match-gripping device connected to the drop whereby the withdrawal of the match moves the drop into position to operate on a succeeding match and ignite the match, and means for feeding the matches into position to be operated by the drop, substantially as set forth.

2. A match-safe comprising a suitable casing, means for presenting a match in position to be withdrawn from the safe and a match-gripping device connected to the match-presenting means whereby the withdrawal of a match moves the match-presenting means into position to operate on a succeeding match, substantially as set forth.

3. A match-safe comprising a suitable casing, a reciprocating drop, a fuel mechanism operated by the drop, whereby the matches are fed one by one into position to be filled by the drop and a match-gripping device connected to the drop whereby the withdrawal of a match moves the drop into position to operate on a succeeding match, substantially as set forth.

4. A match-safe comprising a suitable casing, a drop having a limited rising-and-falling movement within the casing, means for feeding the matches into position to be engaged by the drop during its falling movement, gripping-jaws connected to the drop, the drop being provided with an offset in position to tilt a match into position between the jaws with one end of the match exposed exterior to the casing, and means for feeding the matches into position to be engaged by the drop, substantially as set forth.

5. A match-safe comprising a suitable casing, a gripping device for engaging the match to be withdrawn, means connected to the gripping device for moving a succeeding match into position to be withdrawn, a feeding device and plates spaced apart forming a support for the matches as they are fed into position to be operated upon, substantially as set forth.

698,407. STEERING-GEAR FOR VEHICLES. FRED L. HALL, and RUDOLPH E. HALL, Auburn, Mass., assignors to the Standard Automobile and Manufacturing Company, Auburn, Mass. Filed Nov. 20, 1901. Serial No. 64,644. (No model.)

Claim.—1. In a steering-gear for vehicles a steering-spindle provided with a worm-thread, a nut mounted thereon means for driving the nut in a longitudinal non-rotatable direction a longitudinal rack upon the outer surface of the nut a pinion engaging therewith and mounted on a steering-rod and an adjustable thrust-bearing for the steering-spindle substantially as described.

2. In a steering-gear for vehicles a steering-spindle provided with a worm-thread a nut mounted thereon means for driving the nut in a longitudinal non-rotatable direction a longitudinal rack upon the outer surface of the nut a pinion engaging therewith and mounted on a steering-rod, and an adjustable thrust-bearing for the steering-spindle substantially as described.

3. In a steering-gear for vehicles a steering-spindle provided with a worm-thread a nut mounted thereon a longitudinal rack on the outer surface of the nut a pinion engaging therewith and mounted on a steering-rod and washers on said steering-rod bearing against the surface of the nut substantially as set forth for the purpose specified.

698,408. LIQUID-FUEL BURNER. JOHN W. FERRIS, Louisville, Ky., assignor of one-half to John R. Ferris, Louisville, Ky. Filed Oct. 12, 1901. Serial No. 73,614. (No model.)

Claim.—1. In a liquid-fuel burner, the combination with a substantially trough-shaped fuel-tray having an arched and symmetrically-curved overhanging head, of a shield arranged underneath and in front and rear of the said tray, and a damper comprising a flat plate having an inner flange adapted to rest on the front edge of said shield and support the damper, said damper being arranged to partially close the aperture between the shield and head, substantially as described.

2. In a liquid-fuel burner, the combination with a combined fuel-tray and head consisting of a semi-circular integral casting comprising a lower portion, substantially semi-circular in shape in cross-section and constituting a fuel-tray and an upper portion comprising an arched and symmetrically-curved head, the free end of which extends above and is in front of the free edge of the tray, of means for feeding liquid fuel to said tray, substantially as described.

3. In a liquid-fuel burner, the combination with a combined tray and head consisting of an integral casting, semi-circular in cross-section and having a lower portion, substantially cylindrical in cross-section and constituting a fuel-tray and an upper portion comprising an overhanging arched and symmetrically-curved head, the free end of which terminates at a point in front of and above the free edge of the tray and provided with a vertically-extending portion, substantially as described and for the purpose specified.

698,409. WINDMILL. JOHN FERRIS, Weldon, Iowa, assignor to Henry Ferris, Waukegan, Wis. Filed June 12, 1900. Serial No. 58,798. (No model.)

Claim.—1. A windmill consisting of a frame, one or more wind-vanes provided with fins curved at their outer ends, and attached to a shaft pivoted in the frame, and a wind-collector consisting of a flat surface arranged at an inclination in front of the lower portion of the wheel, combined with steps for adjustably connecting the lower portion of the collector with the frame, whereby the angle of the collector to the wheel may be changed; a tail-vane, an eccentric upon the shaft, and a pump-rod connected to the eccentric and operated thereby, substantially as specified.

2. In a windmill the combination with a frame, of one or more wind-wheels journaled in the frame and provided with curved fins, a horizontally and vertically adjustable wind-collector attached to the frame and adapted to deflect the wind against the fins at the upper half of the wheel, a pump-rod and gearing for operating said rod.

3. In a windmill, the combination with a frame, of one or more wind-wheels journaled in the frame, and provided with fins curved at their ends a wind-collector disposed at an angle in front of the lower half of the wheel and connected to the frame by an upper and lower pair of stays, each of which is horizontally and vertically adjustable to regulate respectively the height, inclination and outward and inward movement of the wind-collector, a pump-rod and means for operating said rod.

698,410. RAILWAY-CROSSING. CHARLES F. FANELL, St. Louis, Mo., assignor to Frederick Fannell, Columbia, Mo. Filed June 28, 1898. Serial No. 65,574. (No model.)

Claim.—1. In a railway-crossing, a movable track-section pivoted at one of its ends to the fixed portion of the track, recesses in the free ends of the movable rails, corresponding projections on the ends of the fixed rails adjacent to the recessed ends of said movable rails, said projections and said recessed ends having transverse openings therein which register with one another, when said projections are covered by said recesses, and a locking device for holding said movable rails in engagement with said fixed rails, comprising a pair of reciprocatory bolts mounted in alignment with said transverse openings in the rails, a rock-shaft, cranks thereon, connected to said bolts, and means for turning said rock-shaft; substantially as described.

2. In a railway-crossing, a movable track-section pivoted at one end thereof to the fixed portion of the track, a cross-bar secured to the free end of said movable section, a pair of posts at the sides of the track adjacent to the pivotal connection of said movable section, a pulley secured to the top of each post, a winch mounted on each post, a pair of cables passing over said pulleys respectively, each cable having one of its ends secured to said cross-bar and its opposite end secured to one of said winches, and weights attached to said respective cables for balancing the weight of said movable track-section, whereby said movable section may be raised by operating the winches and when raised will form a gate across the track containing said movable section, substantially as described.

698,411. PROCESS OF MAKING PEBBLED LEATHER. EMERSON PLAMER, Woodhaven, N. Y. Filed Aug. 28, 1898. Serial No. 73,810. (No specimen.)

Claim.—1. The herein-described process of pebbling leather which consists in scouring to a split of leather pebbles of faceted configuration, securing thereto a surface strip of fabric, and bearding the whole.

2. The herein-described process of pebbling leather which consists

in scouring to a strip of leather pebbles of faceted configuration and of a different leather from the split, securing thereto a surface strip of fabric, and bearding the whole, whereby the grain of the split and the grain of the pebbles are caused to appear through the surface strip.

3. The herein-described process of pebbling leather, which consists in scouring pebbles between two strips of leather, and bearding the whole.

4. The herein-described process of pebbling leather which consists in scouring pebbles of leather between two splits of leather, and bearding the whole.

698,412. ELEVATOR HOISTING MECHANISM. HAROLD BOWYER, Chicago, Ill., assignor to Otto Elevator Company, New York, N. Y., a Corporation of New Jersey. Filed Sept. 28, 1898. Serial No. 59,737. (No model.)

Claim.—1. In an elevator, a car, a pulley yieldingly connected thereto, a counterweight also provided with a pulley, an endless cable operating around said pulleys, a differential pulley, said endless cable passing around said differential pulley, means for driving said differential pulley, and an auxiliary connection between said car and counterweight, as and for the purpose set forth.

2. In an elevator, a car, a pulley, springs connecting said car and pulley, a counterweight also carrying a pulley, an endless cable operating around said pulleys, a differential pulley, said endless cable also passing around said differential pulley, means for actuating said differential pulley, and an auxiliary connection between said car and counterweight, as and for the purpose set forth.

3. In an elevator, a car, a pulley connected to said car for movement relative thereto, a counterweight also carrying a pulley, an endless cable operating around said pulleys, a differential driving-pulley for said cable, an auxiliary cable connecting said car and counterweight, and means for actuating said differential pulley, as and for the purpose set forth.

4. In an elevator, a car, a counterweight therefor, and an endless cable connecting said car and counterweight, in combination with a differential driving-pulley for said cable, comprising a central portion and end portions, said central and end portions cooperating to form pulley-grooves, and means for relatively moving said central and end portions to vary the relative effective driving diameters of said pulley-grooves, as and for the purpose set forth.

5. In an elevator, a car, a counterweight, and an endless cable connecting said car and counterweight, in combination with a differential driving-pulley for said cable, comprising a central portion having beveled ends and end portions having cooperating beveled ends, said bevels forming pulley-grooves, and means for relatively shifting said central and end portions to vary the relative effective driving diameters of said grooves, as and for the purpose set forth.

6. In an elevator, a car, a counterweight, and an endless cable connecting the same, in combination with a shaft, a differential driving-pulley mounted thereon, and comprising a central portion and end portions, said end portions being connected to rotate with said shaft but capable of movement longitudinally thereof and relatively to said central portion, said end and central portions cooperating to form pulley-grooves, and means for shifting said end portions longitudinally of the shaft, whereby the rel-

ative diameter of said pulley-grooves are varied, as and for the purpose set forth.

7. In an elevator, a car, a counterweight, pulleys together respectively carried by said car and counterweight, an endless cable operating over said pulleys, an auxiliary cable also connecting said car and counterweight, means for operating one of said cables, and means for distributing the load between said cables, as and for the purpose set forth.

8. In an elevator, a car, a pulley connected thereto, a counterweight also provided with a pulley, one of said pulleys being yieldingly connected, an endless cable operating over said pulleys, means for actuating said cable, and an auxiliary cable connecting said car and counterweight, as and for the purpose set forth.

9. In an elevator, a car, a counterweight, an endless cable connecting said car and counterweight, an auxiliary cable also connecting said car and counterweight, a differential pulley over which said endless cable operates, means for actuating said pulley, and means for distributing the load between said cables, as and for the purpose set forth.

698,418. CAR-COUPLING. THOMAS A. SAVAGE, Carrollton, Mo., assignor, by direct and mesne assignments, to Morris S. Evans and John W. Weaver, Moline, Ill., Daniel Arthaud, Burlington, Iowa, Charles W. Layman, Lomax, Ill., and Adolph Mueller, Dallas, Ill. Filed July 8, 1901. Serial No. 67,597. (No model.)

Claim.—1. An automatic car-coupler, consisting of a draw-head having in its front end a recess, one of the side walls of said recess being bifurcated at its front end; a knuckle hinged in said bifurcation; an arm secured to the rear face of said knuckle, and having its rear side beveled down nearly to an edge; a finger extending forward from the free end of said arm, said arm adapted to fit close up against the inner face of one of the side walls of said recess; a lock-block adapted to work in said recess and hinged to the opposite wall, opposite the knuckle, and having in its lower face an inclined recess and a vertical rectangular perforation through its free end; a spiral spring, its lower end resting against the upper face of said lock-block, and its upper end against the lower face of the upper wall of said recess; a stop secured to the opposite wall to which the knuckle is hinged, adapted to arrest the finger of the arm mentioned above; an upper wall provided with a vertical oblong rectangular opening; a plate secured to the lower face of said upper wall and parallel with the front wall of said opening; a coupling-pin provided with a dot, and an enlargement at its lower end, forming an upper and lower shoulder and a perforation through its center; said coupling-pin passing through the perforation in the lock-block and rectangular opening; in the upper wall, its lower end resting in a depression in the lower wall; a bolt passing through said lock-block and the perforation in said coupling-pin; a spiral spring working around said bolt, and holding said coupling-pin against the front wall of said rectangular opening; a trip-lever pivoted in the dot of said coupling-pin, and adapted, when raised, to throw the upper shoulder from under the plate secured to said upper wall, thus permitting said coupling-pin and said lock-block to be raised, and the coupler unlocked, substantially as shown and described and for the purposes set forth.

2. An automatic car-coupler, consisting of a draw-head having in its front end a recess, having two side walls, an upper and lower wall, one of the side walls being bifurcated at its front end; a knuckle hinged in said bifurcation; an arm secured to the rear face of said knuckle, and having its rear side beveled down nearly to an edge; a finger extending forward from the free end of said arm; a lock-block hinged to the side wall opposite the bifurcated wall, and having in its under face an inclined recess, and provided with a vertical rectangular opening through its free end; the lower wall, provided with a recess immediately under said opening; a stop secured to the lower wall, opposite the hinged knuckle, adapted to arrest the finger of said arm; the upper wall, provided with an oblong rectangular opening; a plate secured to the lower face of said upper wall and parallel with the front wall of said opening; a coupling-pin provided with a dot, a shoulder below said dot, an enlargement at its lower end, forming an upper and lower shoulder, and a perforation through its center; said coupling-pin passing through the perforation in the lock-block and the rectangular opening in the upper wall; a bolt passing through said lock-block and the perforation in said pin; a spiral spring working around said bolt and holding said coupling-pin against the front wall of said pin; a trip-lever pivoted in the dot of said coupling-pin, and adapted, when raised, to throw the upper shoulder from under the plate secured to

said upper wall, thus permitting said coupling-pin and said lock-block to be raised, and the coupler unlocked, substantially as shown and described and for the purposes set forth.

698,414. SEWING-MACHINE-THREADER. GAN SHAWAN, Bangalore, Mysore, India, assignor to Kant North-Bow, Bangalore, India. Filed Feb. 27, 1908. Serial No. 68,004. (No model.)

Claim.—1. The combination of a thread-guide divided into two parts and having a conical passage for the thread intermediate said parts, a pair of fingers, and means for pressing the fingers together and separating the parts of the thread-guide.

2. The combination of a thread-guide divided into two parts and having a conical passage for the thread intermediate said parts, arms carrying the parts of the thread-guide, a pivot for one of the arms, a pair of pivoted fingers, a spring normally tending to bring the parts of the thread-guide together, and to separate the fingers, and means for pressing the fingers together and separating the parts of the thread-guide.

3. The combination of a thread-guide divided into two parts and having a conical passage for the thread intermediate said parts, arms carrying the parts of the thread-guide, a pivot for one of the arms, a pair of fingers pivoted to one of the arms, a leg fixed to the other arm, and engaging with the tail ends of the fingers, and a spring normally tending to bring the parts of the thread-guide together, and to separate the fingers.

4. The combination of an L-shaped arm, a clamp to which it is pivoted, a thread-guide, one part of which is fixed to the L-shaped arm, a lever and a pair of fingers pivoted to the L-shaped arm, another part of the thread-guide fixed to the lever, a leg on the lever engaging the tail ends of the fingers, and a spring normally tending to bring the parts of the thread-guide together and to separate the fingers.

5. A needle-threader for sewing-machines comprising a thread-guide divided into two parts, a pair of fingers arranged adjacent to one end of the thread-guide, and means for opening and closing the fingers, and for closing and opening the parts of the thread-guide.

698,415. BIT FOR WELL-DRILLING APPARATUS. JAMES W. BLAIR, Oklahoma, Tex., assignor of two-thirds to J. S. Cullman and H. S. Johnston, Oklahoma, Tex. Filed July 22, 1901. Serial No. 68,389. (No model.)

Claim.—1. In combination, a pipe-section, a chisel carried in the lower end thereof and having a portion of its inner face of the same internal diameter as the pipe-section, removable bits arranged in and provided with integral means engaging with the chisel to prevent the dropping down thereof, means pivotally connected to the top of the bits and arranged within and engaging in the wall of the pipe-section for locking the bits in operative position, and a hinge connected to the upper end of said means and adapted when extended to cause said locking means to engage in the pipe-section and when contracted to release the said locking means so the bits can be removed.

2. In a rotary bit, the combination with a pipe-section, of a chisel suitably connected thereto, a pair of bits arranged in said chisel and adapted to extend therefrom, lateral ears integral with the bits and engaging in the chisel to prevent the dropping down of the bits, brace-rods connected at their lower end to said bits and provided with studs adapted to engage in the pipe-section, and a hinge suitably connected with the upper end of said rods and adapted when extended to cause the studs of the rods to engage in the pipe-section for locking the bits in an operative position and when contracted to release the said studs from their engagement with the pipe-section so that the bits can be removed.

3. The combination with a pipe-section, of a chisel connected to the lower end thereof, a pair of removable bits arranged in the said chisel, a

pair of brass-rods connected with the lower end of the bit and engaging in the pipe-section and cooperating with the shoe for locking the bit in an operative position, and means connected to the rods and adapted when extended to cause the said rods to engage with the pipe-section for locking the bit in an operative position and when contracted to release the rods from their engagement with the pipe-section, so that the bit can be removed.

4. A pair of quadrant-shaped bits provided with shoulders and laterally-extending ears, brass-rods pivoted at their lower end to the said bits and provided with studs, a hinge connected to the upper end of the brass-rods, in combination with a brass-shoe adapted to receive the ears of the bits as well as permitting the latter to project therethrough.

5. The combination, with a pipe-section and a shoe connected thereto, of a pair of quadrant-shaped bits provided with shoulders and laterally-extending ears adapted to engage in the shoe for the purpose set forth, a pair of rods, means extending through the lower end of said rods for pivotally connecting the bits thereto as well as together, a hinge adapted to engage in the pipe-section for the purpose set forth, and separate means for connecting the ends of said hinge to the upper end of the said rods.

698,416. BED-BRACE. CHARLES W. SMITH, Piedmont, S. C., assignor of one-half to Samuel Thompson Smith and William F. Hestett, Truroville, Piedmont, S. C. Filed Nov. 13, 1901. Serial No. 28,167. (No model.)

Claim.—1. A bed-brace comprising wires adapted to be connected to the head and foot boards and side rails of a bed, and a tightening device for said wires, consisting of a base-plate having wire-engaging portions thereon extending outwardly at an angle and having a series of openings therein, a rod having a projection thereon adapted to fit within one or the other of said openings, a cross-bar mounted loosely on said rod having wire-engaging portions thereon, and means for moving said cross-bar longitudinally of said rod, the said wires being connected respectively with the wire-engaging portions on said base-plate and said cross-bar.

2. A bed-brace, comprising wires adapted to be connected to the

head and foot boards and side rails of a bed, and a tightening device for said wires consisting of a base-plate having hooks thereon, a series of openings therein, and a perforated flange thereon, a screw-threaded rod extending through said flange and provided with a hook adapted to fit within one or the other of said openings, a cross-bar on said rod having hooks thereon, and a thumb-screw on said rod for moving said cross-bar longitudinally, the said wires being connected respectively with the hooks on said base-plate and with those on said cross-bar.

3. A bed-brace, comprising wires connected respectively to one end and to the adjacent side of the bed at each corner thereof, a centrally-located wire-tightening device, and angularly-arranged wires connected respectively to said wire-tightening device and to the wires at the corners of the bed.

4. A bed-brace, comprising wires connected respectively to one end and to the adjacent side of the bed at each corner thereof, a centrally-located tightening device comprising a base and a part movable longitudinally with respect thereto, angularly-arranged wires connecting said base with the wires at two of the corners of the bed and angularly-arranged wires connecting said longitudinally-movable part with the wires at the other two corners of the bed.

698,417. ELECTRICAL KNIFE-SWITCH. LOUIS J. SMITH, LAWYER, and WILLIAM F. DUNN, Utiex, N. Y., assignors to the Bennett Electric Construction Company, Utiex, N. Y. Filed Nov. 24, 1901. Serial No. 28,705. (No model.)

Claim.—1. A terminal clip for electric switches made from a ribbon blank of sheet-copper, the blank bent near the center of its length to a right angle and one member twisted one-quarter way around to stand centrally with the other member, as set forth.

2. A terminal clip for electric switches made from a ribbon blank of sheet-copper, the blank bent near the center of its length to a right angle and one member twisted one-quarter way around to stand centrally with the other member, as set forth.

3. A terminal clip for electric switches made from a ribbon blank of sheet-copper, the blank bent near the center of its length to a right angle and one member twisted one-quarter way around, and the ends offset as set forth.

4. A terminal clip for electric switches made from a ribbon blank of sheet-copper, the blank bent near the center of its length to a right angle and one member twisted one-quarter way around, and the ends offset, as set forth.

5. A terminal clip for electric switches made from a ribbon blank of sheet-copper folded together and the doubled members bent near the center of their length to a right angle and their ends separated and twisted one-quarter way around, as set forth.

6. A terminal clip for electric switches made from a ribbon blank of sheet-copper folded together and the doubled members bent near the center of their length to a right angle and the members closed from the angle toward the ends to a common, then offset and parallel, and twisted one-quarter way around, as set forth.

7. An electric switch consisting of an insulating-base, terminal clips secured to said base made from a ribbon blank of sheet-copper bent near the center of its length to a right angle and twisted one-quarter way around, the free ends separated and parallel; with a double blade made from a ribbon blank of sheet-copper having a punched central hole with a straight part and enlarged ends, the blank folded through the middle of the said central hole into two parallel blades of the same length and equally spaced apart, secured to a handle by a screw, pivoted to a clip at one end and its inner surfaces adapted to make resilient contact with the outer surfaces of a spring-clip, as set forth.

8. A double blade for an electric switch made from a ribbon blank of sheet-copper, round holes for the wires at each end and a central hole consisting of a straight part with enlarged ends punched therein, the blank folded through the middle of said central hole into two parallel blades of the same length and equally spaced apart the entire length, as set forth.

9. An electric switch consisting of an insulating-base, terminal clips secured to said base, made from a ribbon blank of sheet-copper, the blank bent near the center of its length to a right angle and twisted one-quarter way around, with a blade pivoted to one of said blades and adapted to

close upon the other, the blade secured to a handle by a screw or screw, as set forth.

10. An electric switch consisting of an insulating-base, terminal clips secured to said base made from a ribbon blank of sheet-copper which is bent near the center of its length to an angle and twisted one-quarter way around; with a double blade made from a ribbon blank of sheet-copper, having a punched central hole with a straight part and enlarged ends; the blank folded through the middle of the said central hole into two parallel blades of the same length and equally spaced apart the entire length, the said blades pivoted to a clip and adapted to close upon another clip, and secured to a handle by a screw or screw, as set forth.

11. An electric switch consisting of an insulating-base, terminal clips secured to said base made from a ribbon blank of sheet-copper, which is bent near the center of its length to an angle and twisted one-quarter way around; two double blades each made from a ribbon blank of sheet-copper having a punched central hole with a straight part and enlarged ends, the blank folded through the middle of the said hole into two parallel blades of the same length and equally spaced apart the entire length, the said blades pivoted to a clip at one end and adapted to close upon other clips, and secured to an insulating-bar by means of screws at their opposite ends, the said bar provided with a handle, as set forth.

698,418. POWER-DRIVEN TOOL. RUFUS F. BRADON, Greenville, Miss., assignor to the Garden Hollow Plant Grease Company, Greenville, Miss. Filed Jan. 4, 1908. Serial No. 23,322. (No model.)

Claim.—1. In an instrument of the class described, the combination with a suitable support, of a driving-shaft journaled upon the support, a tool-spindle also journaled upon the support and movable toward and from the driving-shaft, coacting clutch members carried by the shaft and spindle, and a resistance-spring mounted upon the tool-spindle on one side of its clutch member to move said spindle away from the driving-shaft and hold it in engagement with the article operated upon.

2. In an instrument of the class described, the combination with a suitable support, of a driving-shaft journaled upon the support, a tool-spindle also journaled upon the support and movable toward and from the driving-shaft, coacting clutch members carried by the shaft and spindle, and an exteriorly-located resistance-spring mounted upon the tool-spindle on one side of its clutch member and bearing against the frame, said spring being arranged to move the spindle away from the driving-shaft and hold it in engagement with the article operated upon.

3. In an instrument of the class described, the combination with a suitable support, of a driving-shaft journaled upon the support, a tool-spindle also journaled upon the support and movable toward and from the driving-shaft, coacting clutch members carried by the shaft and spindle, an exteriorly-located resistance-spring mounted upon the tool-spindle and bearing against the frame, said spring being arranged to move the spindle away from the driving-shaft and hold it in engagement with the article operated upon.

the away from the driving-shaft and hold it in engagement with the article operated upon, and means for adjusting the tension of the spring.

4. In an instrument of the class described, the combination with a suitable support, of a driving-shaft journaled upon the support, a tool-spindle also journaled and longitudinally movable on the support in alignment with the driving-shaft, said spindle having one end adjacent to and in line with one end of the shaft, coacting clutch members carried by the adjacent ends of the driving-shaft and tool-spindle, and means engaging the tool-spindle and the support to move said spindle away from the driving-shaft.

5. In an instrument of the class described, the combination with a suitable support, of a driving-shaft journaled on the support, a tool-spindle also journaled and longitudinally movable on the support in alignment with the driving-shaft, said spindle having one end located adjacent to and in line with one end of the shaft, coacting clutch members carried by the adjacent ends of the driving-shaft and tool-spindle, and a coiled spring surrounding the spindle and bearing against the same and the support to move said spindle away from the driving-shaft and maintain it in operative relation to the article operated upon.

6. In an instrument of the class described, the combination with a suitable support, of a driving-shaft journaled on the support, a tool-spindle also journaled and longitudinally movable on the support in alignment with the driving-shaft, said spindle having one end located adjacent to and in line with one end of the shaft, coacting clutch members carried by the adjacent ends of the driving-shaft and tool-spindle, a collar adjustably mounted upon the spindle, and a coiled spring surrounding the spindle and bearing against the collar and the support to move the spindle away from the driving-shaft and maintain said spindle in operative relation to the article operated upon.

7. In an instrument of the class described, the combination with a casing having a handle, of a shaft journaled in the casing, a tool-spindle projecting from the casing and movable toward the shaft, and coacting clutch members carried respectively by the inner ends of the spindle and shaft, said members being located within the casing, the member of the spindle being movable into and out of engagement with the shaft member upon the movement of said spindle.

8. In an instrument of the class described, the combination with a casing having a handle at one end, of a tool-spindle rotatably mounted in the other end of the casing and longitudinally movable therein, power-transmitting means passing through the side of the casing, clutch members secured respectively to the inner end of the tool-spindle and the power-transmitting means, said clutch members being located within the casing and one of said members being movable into and out of engagement with the other, and means for holding the tool-spindle in operative engagement with the article operated upon.

9. In an instrument of the class described, the combination with a casing, of a driving-shaft journaled in the casing, a tool-spindle rotatably and slidably mounted in the casing in alignment with the shaft, the inner ends of said shaft and spindle being located within the casing, coacting clutch members carried by the adjacent inner ends of the shaft and spindle, the clutch member of the spindle being movable into and out of engagement with the shaft member upon the longitudinal reciprocation of said spindle, and adjustable yielding means engaging the spindle to move it outwardly, and maintain it in operative engagement with the article operated upon.

10. In an instrument of the class described, the combination with a casing having a head at one end, of a shaft journaled in the casing and having a clutch member at its inner end, a spindle rotatably and slidably mounted in the head of the casing, a clutch member secured to the inner end of the spindle and having one face coacting with the clutch member of the shaft, and means engaging the exposed end of the spindle to move said spindle away from the driving-shaft and maintain it in operative engagement with the article operated upon.

11. In an instrument of the class described, the combination with a casing having a head at one end, of a shaft journaled in the casing and having a clutch member at its inner end, a spindle rotatably and slidably mounted in the head of the casing, a clutch member secured to the inner end of the spindle and having one face coacting with the clutch member of the shaft, and the other coacting with the inner face of the head as the spindle is moved in one direction or the other to respectively rotate said spindle and hold it against rotation, and a spring located upon the projecting portion of the spindle and bearing against the same and the casing to move the spindle outwardly and maintain it in operative engagement with the article operated upon.

698,419. GRINDING. BRADSHAW EATON, New York, N. Y., assignor to Francis A. Bradshaw, Cambridge, Mass. Filed July 10, 1901. Serial No. 23,323. (No model.)

Claim.—1. A disk-wheel unit, comprising a receptacle for water, a

pointed lower lip, and a projecting flange shaped and adapted to come in contact with the buttends of the ear below the said lip, substantially as described.

2. A slot-room wheel, comprising a receptacle for wire, a pointed lower lip, and a projecting flange below the said lip provided with a gutter, substantially as described.

3. A slot-room wheel, comprising a receptacle for wire provided with upwardly-sloping sides, a lower lip drawn inward and forward from the said sloping sides, and coming to a point in front and a projecting flange shaped and adapted to come in contact with the buttends of the ear below the said lip, substantially as described.

398,490. MACHINE FOR APPLYING GATHERING-STRINGS TO BAGS. JAMES W. TAYLOR, Goldsboro, N. C., assignor of three-fourths to George Alexander Howard, Jr., Thomas Hall Holmes, and John Syner, Goldsboro, N. C. Filed Apr. 4, 1901. Serial No. 54,571. (No model.)

Claim.—1. In a machine of the character described, the combination of a bag-clamping device, and a shaft with which it is adapted to swing, of a pinion keyed upon the pivot-shaft, a cam fixed in position relatively to said pinion, a vertically-slidable rack-bar engaging the said pinion, a rotary propelling medium, and means connecting the latter with the said rack-bar, whereby the bag-clamp is swung into vertical position and closed and opened, substantially as shown and described.

2. In a machine of the character described, the combination with a swinging bar having one end connected to a horizontal jaw, of a lever-able bar adapted to slide on the swinging bar and having a corresponding jaw, a spring for returning the movable bar whereby the jaws are held normally opened, means for swinging the bag-clamp as described, and a fixed cam arranged as described and adapted to engage the sliding bar for closing the jaws upon a bag.

3. In a machine of the character described, the combination with an endless traveling bag-carrier composed of a series of plates or sections joined together, of a supporting-frame and rotatable means arranged at the ends thereof for supporting the carrier as specified, and bag support-

ing and stretching device adapted to said sections, one of said devices being movable toward and from the other, and means for shifting such device, substantially as shown and described.

4. In a machine of the character described, the combination of a movable bag-carrier proper, of bag-supporting and stretching pins arranged vertically, one of said pins being movable toward and from the other, and means for automatically shifting the movable pin for stretching and then releasing a bag, substantially as shown and described.

5. In a machine of the character described, the combination with a movable bag-carrier having pins for holding and stretching bags as specified, one of said pins being movable toward and from the other, a cam arranged horizontally and parallel to the carrier, and means connected with the movable pin for engaging said cam, whereby, as the carrier advances, the movable pin is shifted to stretch a bag, substantially as shown and described.

6. In a machine of the character described, the combination with an endless traveling bag-carrier comprising a series of plates or sections joined together, a series of pins of pins carried by the several sections, one of the same being movable toward and from the other, a cam arranged beneath the carrier and adapted to yield to pressure as specified, and movable pins having pendulous portions adapted to engage the cam, substantially as shown and described.

7. In a machine of the character described, the combination with a rotatable supporting-frame, of an endless bag-carrier having a series of plates joined together, bag holding and stretching pins applied to each plate or section, one of said pins being movable and held in a block adapted to slide transversely of a section, an arm or stud pendulous from each sliding block, and a cam arranged beneath the carrier and adapted to engage each stud or arm, substantially as shown and described.

8. In a machine of the character described, the combination with a rotatable supporting-frame, of an endless traveling bag-carrier comprising plates or sections joined together and having a transverse dovetail groove, a fixed pin arranged on each section, a block adapted to slide in the above-said groove and having a vertical pin and a pendulous arm or stud projecting through a transverse slot in the section, a cam arranged horizontally beneath the carrier and having rounded or bent ends, horizontal guides attached to the frame, and projecting toward the cam, supports for said cam which are adapted to slide in said guides, and springs for pushing the cam laterally, whereby the tension is applied to the bags while held by the pins, substantially as shown and described.

9. In a machine of the character described, the combination with an endless traveling bag-carrier, of pins of pins held thereon, one of each pair being movable laterally, means for shifting the movable pin for holding the bag under due tension when required, and a fixed cam adapted to act upon a pendulous portion of the movable pin for shifting them toward the fixed pin, to release tension on the bags, substantially as shown and described.

10. In a machine of the character described, the combination with needles adapted to reciprocate horizontally, of a spring-clamp for holding a string, a swinging device adapted to engage the string while so held and draw off a portion of the same, and a vertically-reciprocating device working between the needles and adapted to engage the string while drawn across them and to carry the same down into the eyes of the needles, substantially as shown and described.

11. In a machine of the character described, the combination with needles adapted to reciprocate horizontally, of a spring-clamp for holding the string temporarily, of a catch adapted to the said clamp below its mouth, a device for drawing off the string from the said clamp and means for pulling the string downward to cause it to engage the catch and enter the eyes of the needles, substantially as shown and described.

12. In a machine of the character described, the combination with needles adapted to reciprocate horizontally and provided with spring-latches normally closing their eyes, the means for holding a string temporarily, and means for drawing off the same, and a puller adapted to work adjacent to the needles and to engage the string and draw the same down against the pressure of the spring-latches, substantially as shown and described.

13. In a machine of the character described, the combination with needles adapted to reciprocate horizontally, of fixed spring-clamps having sliding jaws and arranged vertically, means for automatically opening the said jaws, and a swinging clamp adapted to pass between the fixed clamps and to engage a string held by the latter, the said swinging clamp being itself provided with means for opening its jaws and releasing the string at the proper juncture, substantially as shown and described.

14. In a machine of the character described, the combination with needles adapted to reciprocate horizontally, of fixed spring-clamps arranged as described, central pins adapted to move vertically for opening the clamps, means for engaging the lower ends of said pins for the purpose of opening the clamps, and suitable mechanism for drawing off the

string and into the eyes of the needles, substantially as shown and described.

15. In a machine of the character described, the combination with needles adapted to reciprocate horizontally and means for placing a thread in the needles, of fixed spring-clamps, central pins adapted to reciprocate for opening the clamps, tappets arranged below said pins, a rock-shaft whereby the said tappets are moved, a lever-arm applied to the said rock-shaft, and means for rotating the latter for opening the clamps at the required time, substantially as shown and described.

16. In a machine of the character described, the combination with needles adapted to reciprocate horizontally, of spring-clamps adapted for holding the string temporarily, means for opening the clamps, a swinging device which engages the string for drawing it off and across the needles as specified, and a vertically-movable device adapted to engage the string and for pulling it into the eyes of the needles, and means for connecting the said movable device with the above-said means for opening the clamps, substantially as shown and described.

17. In a machine of the character described, the combination with fixed string-clamps, of a swinging clamp composed of spring-jaws and a slidable pin adapted to open the latter, the said pin projecting as specified, and the said clamp being adapted to swing between the fixed clamps for closing and drawing off the string, and a fixed projection or bracket upon which the swinging clamp strikes when thrown back to its normal position, whereby the string is drawn across the needles and then released, substantially as shown and described.

18. In a machine of the character described, the combination with a clamp for holding a string temporarily, of a device for drawing off the string across the needles, mechanism for operating such device, and means for pulling the string downward into the eyes of the needles while held between the clamps, substantially as shown and described.

19. In a machine of the character described, the combination with needles adapted to reciprocate horizontally, of a fixed string-clamp, a movable clamp for drawing off the string across the needles, a hook adapted to work adjacent to the needles, a cam for raising the said hook at the proper time, and means for operating the said movable clamp, substantially as shown and described.

20. In a machine of the character described, the combination with means for holding and stretching a bag and means for inserting a string, of a vertically-movable block or device adapted for contact with the base of the bag adjacent to one of the holding devices, whereby said base is drawn or brought into the same horizontal position, for the purpose specified.

21. In a machine of the character described, the combination with a movable bag-carrier having a series of pins of pins for holding and stretching the bags and needles for inserting strings, of a vertically-movable device adapted to project upward through slots in the carrier and have contact with the base of the bags adjacent to the pins where the needles enter, whereby the base of the bags are brought into a like position, substantially as shown and described, for the purpose specified.

22. In a machine of the character described, the combination with needles for inserting string and an endless traveling bag-carrier, comprising a series of plates or sections binged together and provided with openings and with a series of pins of pins for holding the bags, of a vertically-movable block carrying pins of pins, one of each pair being movable laterally, and means for effecting such lateral movement after the said pins have entered the base of the bags, whereby the base are drawn preparatory to the entrance of the needles, substantially as shown and described.

23. In a machine of the character described, the combination with string-carrying needles, a movable bag-carrier and device for holding the bags thereon, of means for projecting upward through the carrier and engaging the base of the bags for drawing them preparatory to entrance of the stringing-needles, substantially as shown and described.

24. In a machine of the character described, the combination with a traveling bag-carrier and needles for inserting string in bags, of a block adapted for contact with the base of bags while held on the carrier, whereby said base are moved in a horizontal plane, fixed points projecting from said block, and movable points arranged alongside the same, substantially as shown and described, whereby the bag-bases are moved and placed for distention simultaneously, as specified.

25. In a machine of the character described, the combination with needles carrying string and the bag-carrier and means for holding bags duly stretched thereon, of two pairs of beam-pleating points, each pair being composed of two separate points which are hinged and formed on their opposite sides as shown, one of the points of each pair being movable laterally, and means for effecting such movement, substantially as shown and described.

26. In a machine of the character described, the combination with a bag-holder and needles for inserting string, of pins of pins placed and distending points, one of each pair being movable laterally, a vertically-

movable bar by which said points are moved, and laterally-slidable blocks held on the vertically-movable bar and carrying the movable points, and means for automatically separating the sliding blocks, substantially as shown and described.

27. In a machine of the character described, the combination with needles for inserting string, and an endless traveling bag-carrier and pins of pins supported thereby, of a vertically-movable part carrying pins of beam-pleating points, one of each pair being movable laterally, slidable blocks arranged horizontally on said movable part, a wedge adapted to enter between said movable blocks for separating them for the purpose of distending the bag-bases, means for raising the movable part and forcing the wedge upward at the right juncture, and means for returning the movable blocks after the base has been distended, substantially as shown and described.

28. In a machine of the character described, the combination with needles for inserting string, and an endless traveling bag-carrier having a series of pins of pins of pins, of a vertically-movable part carrying fixed points for placing the base of the bags, movable points arranged normally in contact with the fixed ones, laterally-movable blocks carrying the movable pins and sliding in the dovetail ways in said movable part, a wedge arranged vertically in a dovetail way and adapted to force the said movable blocks aside, and means for separating the said movable part and the wedge in the order specified.

29. In a machine of the character described, the combination with string-inserting devices and an endless traveling bag-carrier having a series of plates or sections binged together and provided with a notch or groove, of a device adapted for entering such notch or groove for the purpose of locking the individual sections, substantially as shown and described.

30. In a machine of the character described, the combination with an endless traveling bag-carrier having a series of plates or sections which are joined together and provided with pins for daily holding and stretching a bag, and also constructed with a transverse groove or notch, of a locking-bar arranged at the side of the frame horizontally, and adapted to enter such groove or notch, needles arranged adjacent to the locking device, the point of the latter being in advance of them of the needles, whereby said sections are locked preparatory to engagement of the needles with a bag, substantially as shown and described.

31. In a machine of the character described, the combination with an endless traveling bag-carrier having sections or plates provided with a transverse dovetail groove and bag-supporting pins arranged adjacently, of a locking-bar adapted to enter and traverse said groove, needles arranged parallel to the locking-bar and adapted to traverse the sections, and means for operating the said locking device and needles simultaneously, substantially as shown and described.

32. In a machine of the character described, the combination with an endless traveling bag-carrier composed of a series of sections or plates binged together and carrying bag-holding pins, as specified, of means for locking the carrier as a whole, and a device for locking on individual sections thereon, and needles arranged alongside each device and adapted to coast with the pins of the sections when thus locked, substantially as shown and described.

33. In a machine of the character described, the combination with string-inserting devices and a movable bag-carrier, of means for moving the same as a whole and locking the moving agent, and means for locking on individual sections thereof preparatory to the action of the bag-stringing mechanism, substantially as shown and described.

34. In a machine of the character described, the combination with an endless traveling bag-carrier comprising a series of sections binged together and provided with a transverse groove, and bag-holding pins arranged adjacent to said groove, a locking-bar adapted to enter the groove, needles arranged parallel to said bar, and a common head to which the bar and needles are rigidly attached, and a means for imparting due depression to both devices, substantially as shown and described.

35. In a machine of the character described, the combination with the frame having horizontal carriage as specified, of an endless traveling bag-carrier supported in said carriage, a bracket extending laterally from the said frame and provided with a guideway as specified, of a locking device and needles rigidly connected and means for reciprocating them on the said bracket and across the bag-carrier, substantially as shown and described.

36. In a machine of the character described, the combination with the endless traveling bag-carrier composed of the plates or sections which are joined together and each provided with a longitudinal dovetail groove, and a locking device, of a plate 21 which is slidable in said groove and carries a bag-holding pin, means for moving said plate automatically as the bag-carrier advances, fixed pins on said plates or sections, and means for moving the bag-carrier-independently, substantially as shown and described.

698,491. BRAKE-CHOC MECHANISM. EMORY TRENTHAM, Dayton, Ohio, assignor to the Darnley & Smith Car Company, Dayton, Ohio. Filed Jan. 27, 1905. Serial No. 51,571. (No model.)

Claim.—1. The combination with a wheel, of a brake-choc adapted to engage the periphery thereof and being of differential thickness throughout its length to compensate for the difference between the area in which its opposite ends travel, a brake-head carrying the brake-choc, an oscillating brake-hanger to which the brake-head is rigidly secured and a support for the brake-hanger.

2. The combination with a wheel, of a brake-hanger, a brake-head rigidly secured thereto, a bearing for the brake-hanger and in which the same is rotatably mounted, a suitable support for said bearing, a brake-choc carried by the brake-head and being of differential thickness throughout its length to compensate for the difference between the area in which its opposite ends travel in its movement toward the center of the wheel, and means for applying the brake-choc to the wheel.

698,492. WAREHOUSE STAND OR HOLDER. WILLIAM W. TWILLEY, Dover, Mass., assignor to Albert F. Olney, Dover, Mass. Filed Jan. 9, 1905. Serial No. 50,945. (No model.)

Claim.—1. In a warehouse support or holder, the combination with U-shaped crossed supporting members having lateral extensions and detachably connected together, of bracing detachably connected to the base of the crossed supporting members, said legs detachably held by the lateral extensions of the crossed supporting members and the ends of the bracing.

2. In a warehouse support or holder, the combination with crossed supporting members detachably connected together and having extensions, of legs comprising sleeves detachably connected to said extensions, lower leg portions telescoping in said sleeves, clamping-devices for securing the legs in the sleeves at different heights, and bracing connected to the crossed supporting members which bracing extend in holding the legs in operative position.

3. In a warehouse support or holder, the combination of U-shaped crossed supporting members detachably connected together and having extensions, crossed bracing detachably connected to the U-shaped supporting members and provided with perforations or apertures, and supporting-legs comprising upper sleeve portions having their lower parts located in the apertures of the bracing and their upper parts extending through the lateral extensions of the U-shaped supports, means for securing said sleeves against displacement, lower leg portions telescoping in the sleeves, and clamping devices for securing the lower leg portions to the sleeves at different heights therein.

698,498. CRANE AND SCAFFOLDING. SAMUEL T. WILLIAMS, John W. Weaver, and CHARLES H. WILLIAMS, Cleveland, Ohio. Filed Dec. 17, 1897. Serial No. 60,397. (No model.)

Claim.—1. In a crane-supporting structure, the combination of a scaffolding carrying horizontal girders, a crane supported thereon, said crane being carried on wheels constructed to run between and upon adjacent pairs of said girders, substantially as described.

2. In a crane-supporting structure, the combination of a scaffolding having its upper portion connected by sets of horizontal girders, the girders of each set being vertically over one another and having bracing members extending between them, with a crane supported by said scaffolding having wheels placed to run between the girders of said sets, substantially as described.

3. The combination of a scaffolding, a series of upper rails and a series of lower rails mounted on the scaffolding, tracks having wheels adapted to the space between the two sets of rails, a crane carried by said tracks and having overhanging girders and a trolley adapted to travel on the girders, substantially as described.

4. The combination of a scaffolding, rails thereon, two tracks having wheels adapted to the rails, the base-frame of a crane, and a horizontal pivot-pin securing each track to the base-frame, substantially as described for the purpose set forth.

5. The combination of a scaffolding carrying rails and longitudinal trunks and a substantially horizontal framework having a trunk provided with wheels for supporting each of the corners of said framework, said tracks running on said rails, vertical members carried by the framework and a crane structure supported by said vertical members, gear-wheels carried by the framework, and means for revolving said wheels and thereby causing the framework with its attached parts to move over the scaffolding, substantially as described.

698,494. TELEGRAPH-POLE OR FENCE-POST. IRVING H. WADSWORTH, Union City, Mich., assignor to Frank C. Eaton, Union City, Mich. Filed Aug. 27, 1891. Serial No. 73,499. (No model.)

Claim.—1. The combination with an anchor, of a threaded rod carried by said anchor, a pole or post having in its lower end a base adapted for the reception of said threaded rod, a base-plate through which the rod extends, guys extending from the base-plate to an upper portion of the pole or post, and adjusting-nuts on said threaded rod, said nuts bearing against the upper surface of the base-plate and the bottom of the pole respectively.

2. The combination with an anchor, of a base, a threaded rod carried by the anchor and extending through an opening in the base-plate, a nut on said threaded rod bearing against the upper surface of the base-plate, a pole or post supported by said threaded rod, and guys extending from the base-plate to an upper portion of said pole or post.

3. The combination with a base-plate, of a pole, means for adjusting said pole vertically, and guys passing centrally through openings in the pole and having their lower ends attached to the base-plate.

4. The combination of the base-plate, a pole or post vertically adjustable with respect thereto, and guys having their central portions attached to an upper portion of the pole or post, the lower ends of said guys being arranged on opposite sides of the post and secured to said base-plate.

5. The combination with a pole or post, of an upper wire-carrying section adjustable at an angle with respect to said pole or post, and means for locking said wire-carrying section in any position to which it may be adjusted.

6. The combination with a pole or post, of an upper wire-carrying section slanting thereto, a segmentally-shaped plate carried by the pole or post and a locking-bolt secured by the adjustable section and adapted to said plate.

7. The combination, in a device of the class specified, of a cross-arm slanting to the pole or post, a continuous brace secured at its opposite ends to the cross-arm, and means for locking said brace in an adjusted position.

8. In a device of the class specified, a cross-arm centrally slanting to the pole or post, a continuous flexible brace passing through an opening in said pole and having its opposite ends secured in the cross-arm, and a nut-screw for locking said brace in position.

698,495. ACETYLENE-GAS GENERATOR. ARTHUR YANNEY, New Orleans, La., assignor to the Tinsley Generator Co., New Orleans, La. Filed Feb. 6, 1901. Serial No. 65,517. (No model.)

Claim.—1. In an acetylene-gas generator, the combination of a tank, a generator and a gasometer in communication with each other and both located in said tank, a carbide-hopper, a feed-controlling device for the hopper, a jacket in said generator, connections between the feed-controlling device and the gasometer, including a substantially U-shaped rod located in part by said jacket, a tube in the jacket projecting through the generator and insulating a part of said rod and a pipe connected with said jacket and having its inlet in said tank.

2. In an acetylene-gas generator, a tank, a generator and a gasometer in communication with each other and both located in said tank, a carbide-hopper, a feed-controlling device for the hopper, a jacket in said generator, connections between the feed-controlling device and the gasometer, including a substantially U-shaped rod located in part by said jacket, a tube in the jacket projecting through the generator and insulating a part of said rod and a pipe connected with said jacket and having its inlet in said tank.

3. In an acetylene-gas generator, a tank, a generator and a gasometer in communication with each other and both located in said tank, a carbide-hopper, a feed-controlling device for the hopper, a jacket in the generator a lever connected with the gasometer, a flexible connection united to the lever and framework respectively, a U-shaped rod located in part by said jacket, a tube in the jacket to receive a branch of said rod and passing through the generator, a pulley connected to said rod and receiving said flexible connection, and means to convey water into said jacket.

4. In an acetylene-gas apparatus, a carbide-containing hopper having a plurality of superposed conical bottoms of decreasing obtuseness toward the lower one, a conical member located by the lower bottom, a flexibly-suspended cone in said hopper, a second cone for operating the flexibly-suspended cone, and means for actuating said second cone.

5. In an acetylene-gas apparatus, a carbide-containing hopper having a plurality of superposed conical bottoms of decreasing obtuseness toward the lower one, a conical member located by the lower bottom, a flexibly-suspended cone in said hopper, a second cone for operating the flexibly-suspended cone, a gasometer, a generator to which said hopper is connected and in communication with said gasometer, and operative connections between said second cone and the generator.

6. In an acetylene-gas apparatus, a hopper having a plurality of angularly-disposed and detachably-connected, superposed bottoms, a conical reinforcing-plate in the lower bottom, a cone flexibly supported in said hopper, a second cone arranged below and adapted to engage the first cone, and means for operating said second cone.

DESIGNS.

35,877. HANDLE FOR SPOON, FORK OR SIMILAR ARTICLES. WILLIAM E. CARROLL, Concord, N. H., assignor to William E. Durgin Company, Concord, N. H. Filed Jan. 27, 1902. Serial No. 91,664. Term of patent 7 years.

Claim.—The design for a handle for a spoon, fork or similar articles, substantially as shown and described.

85,878. DECANTER. ALBERT FINE, Chicago, Ill. Filed Feb. 17, 1902. Serial No. 94,002. Term of patent 7 years.

Claim.—The design for a decanter, substantially as herein shown and described.

85,879. RING. FRED J. GARDNER, New York, N. Y., assignor to E. A. GARY COMPANY, New York, N. Y. Filed Mar. 26, 1902. Serial No. 94,041. Term of patent 24 years.

Claim.—The design for a ring, substantially as herein shown and described.

85,880. TOY. GEORGE A. FINE, Detroit, Mich. Filed Mar. 21, 1902. Serial No. 100,002. Term of patent 24 years.

Claim.—The design for a toy, herein shown and described.

85,881. FRAME FOR MOUNTING PICTURES. HENRY RABENHORN, Brooklyn, N. Y., assignor to Royal Metal Furniture Company, Brooklyn, N. Y., a Corporation of New York. Filed Mar. 12, 1902. Serial No. 94,114. Term of patent 7 years.

Claim.—The design for a frame for hanging pictures, substantially as herein shown and described.

TRADE-MARKS

REGISTERED APRIL 22, 1902.

88,144. BEER. BREWERY COMPANY, New York, N. Y. Filed Feb. 1, 1902.

JOHN CLARK RIDPATH

Essential feature.—The name "JOHN CLARK RIDPATH," associated with the portrait of said Ridpath. Used since October, 1900.

88,145. ARTIST MATERIALS AND EQUIPMENT. GEORGE WAGNER, Bismarck, Germany. Filed Mar. 22, 1902.

Pelican

Essential feature.—The word "PELICAN." Used since December, 1900.

88,146. IMPROVED PHOTOGRAPHY PAPERS AND PHOTOGRAPH DEVELOPERS. RICHARD BROWN, New York, N. Y. Filed May 21, 1901.

ROTOGRAPH

Essential feature.—The word "ROTOGRAPH." Used since October, 1900.

88,147. CIGARETTES. RICHARD BROWN, New York, N. Y. Filed Mar. 12, 1902.

Essential feature.—The representation of a key in a shoe of open. Used since October 20, 1901.

88,148. WIRELESS ELECTRIC COOKING. RICHARD BROWN, New York, N. Y. Filed Mar. 12, 1902.

Essential feature.—The word "CHENEBROOK MUSEUM" and the representation of a key in a shoe of open. Used since February 4, 1900.

88,149. CIGARETTES. RICHARD BROWN, New York, N. Y. Filed Mar. 12, 1902.

La Beauté

Essential feature.—The word "LA BEAUTÉ." Used since December, 1900.

88,150. CIGARETTES. RICHARD BROWN, New York, N. Y. Filed Mar. 12, 1902.

KORSO

Essential feature.—The word "KORSO." Used since September 21, 1901.

88,151. HOBART. THE KAPPA BETA & DORA HOBART Co., Dec-
den and Knoxville, Ohio. Filed Mar. 6, 1902.

Essential feature.—The representation of the head of an oak sur-
rounded by two concentric bands. Used since June, 1901.

88,152. CARTERS AND WINE-SUPPLIERS. EARL CUTHBERT
New York, N. Y. Filed Mar. 6, 1902.

Essential feature.—The words "THE SUN" and a representation
of the sun. Used since September, 1901.

88,153. CERTAIN NAMED SHOES. J. E. GUN SHOE Co., Atlanta,
Ga. Filed Mar. 12, 1902.

RED SEAL

Essential feature.—The representation of a seal colored red or the
words "RED SEAL," singly or jointly. Used since January 1, 1900.

88,154. WOMEN'S, MEN'S, AND CHILDREN'S SHOES. EASTMAN
SHOE MFG. Co., Burlington, N. J. Filed Feb. 17, 1902.

Essential feature.—The word "PEAR" and the representation of a
pear. Used since 1894.

88,155. BOOTS, SHOES, AND SLIPPERS. NEWELL WOODBURY
Beverly, Mass. Filed Oct. 14, 1901.

HOP-SCOTCH

Essential feature.—The compound word "HOP-SCOTCH" and the
representation of the diagram of the game hopscotch. Used since
January 1, 1902.

88,156. BOOTS AND SHOES. LEWIS A. GUNNET, North Abing-
ton, Mass. Filed Mar. 10, 1902.

LONG LIFE.

Essential feature.—The compound word "LONG-LIFE." Used
since January 10, 1901.

88,157. HEEL AND SOLE PROTECTORS FOR BOOTS AND SHOES.
THE GARDNER MFG. Co., Boston, Mass. Filed Mar. 7, 1902.

CIRCLETTE

Essential feature.—The word "CIRCLETTE." Used since July
15, 1902.

88,158. LACIERS. CHARLES E. HEDGECOCK, Chattanooga, Tenn.
Filed Feb. 4, 1902.

Chas. E. Hedgcock

Essential feature.—The facsimile signature of the registrant. Used
since January 6, 1902.

88,159. PUDDING-TARTS AND BAKING PREPARATIONS.
THE E. J. BACCHINI Co., Inc., Boston, Mass. Filed Feb. 21, 1902.

Wonderland

Essential feature.—The word "WONDERLAND." Used since
September 2, 1901.

88,160. PUDDING-TARTS AND BAKING PREPARATIONS.
THE E. J. BACCHINI Co., Inc., Boston, Mass. Filed Feb. 21, 1902.

Essential feature.—The representation of a fairy. Used since Sep-
tember 2, 1901.

88,161. CERTAIN NAMED FOOD PREPARATIONS. BROWN-CARVER
Co., New York, N. Y. Filed Feb. 26, 1902.

Essential feature.—The word "FOUNTAIN." Used since Jan-
uary 2, 1902.

88,162. WHISKY, WINE, MALTED LIQUORS, AND NON-ALCO-
HOLIC BEVERAGES. CLAYTON WHISKY, New York, N. Y. Filed Feb.
26, 1902.

Essential feature.—The words "LITTLE GOOD" and the picture
of a wine-bottle, including the figure of a star in front of a cork. Used
since July, 1900.

88,163. CERTAIN NAMED MEDICAL COMPOUNDS. CHARLES
WHEAT & LANE, Hammond, Ind. Filed Feb. 4, 1902.

Essential feature.—The word "DERMACILIA" in connection with
the representation of a man seated in front of a microscope standing on a
table. Used since May 1, 1900.

88,164. REMEDY FOR GOUT. FRANK J. KIRKMAN, Baltimore,
Md. Filed Mar. 4, 1902.

88,164.

Essential feature.—The portrait of the registrant. Used since Au-
gust 1, 1901.

88,165. REMEDY FOR CERTAIN NAMED DISEASES. DR.
JOHN A. BARNES, Peoria, Ill. Filed Feb. 26, 1902.

Essential feature.—The words "THE POCKET DRUG STORE" and
a diamond shape including figure. Used since January 15, 1902.

88,166. HAIR-REMOVING APPLICATIONS FOR THE HAIR
AND COMPLEXION. MARY T. CHAMBERLAIN, St. Paul, Minn. Filed Mar. 2,
1902.

Essential feature.—The representation of a woman's head with long
hair flowing down, light on one side and dark on the other, and a band
below the head. Used since March 1, 1901.

88,167. CALCULATED OF SOME EARLY BARTER. VERMONT
CHOCOLATE & CO., CHOC. MFG. CO., FRANKFURT-ON-MAIN, GERMANY. Filed Mar. 11, 1902.

DYMAL

Essential feature.—The word "DYMAL." Used since February,
1901.

88,168. LAUNDRY SOAP. HALL'S CITY SOAP WORK, Newmarket,
N. H. Filed Nov. 12, 1901.

HARD
MAPLE

Essential feature.—The words "HARD MAPLE." Used since
March 1, 1900.

88,169. **BLENDING POWDER, AND BLENDING**
POWDER. WILLIAM E. BROWN, Philadelphia, Pa. Filed Dec. 21, 1901.

HOUSEHOLD

Essential feature.—The word "HOUSEHOLD." Used since November, 1901.

88,170. **BLENDING PREPARATION.** T. C. & S. Co., London, India, and London, England. Filed Mar. 22, 1902.

ORITE

Essential feature.—The word "ORITE." Used since September 11, 1901.

88,171. **STICK, FLASK, AND FLASK BOTTLE-DRINKING PREPARATION.** HENRI L. LLOYD, Detroit, Mich. Filed Mar. 24, 1902.

Essential feature.—The word "BULL DOG" and the representation of the head of a bulldog. Used since November, 1901.

88,172. **VARNISHES, WOOD-FILLERS, WOOD-STAINERS, AND PAINTS.** STANDARD VARNISH WORKS, New York, N. Y. Filed Mar. 21, 1902.

Essential feature.—A polygonal figure having parallel top and bottom lines and retreating angles at its opposite ends. Used since March 14, 1902.

88,173. **RETORTING COAL.** FINE HANCOCK COAL COMPANY, England, Mich. Filed Oct. 4, 1901.

Essential feature.—The representation of a geometric shield on which is two concentric red circles, the space within the inner circle being cross-sectioned by diagonal lines and a plain band with red borders superimposed upon said circles. Used since August 13, 1901.

88,174. **STICK FOR GRASS FOR PRINTING-PRESS.** BARKER BROTHERS & COMPANY, Chicago, Ill. Filed Mar. 9, 1902.

SILVER GLOSS

Essential feature.—The word "SILVER GLOSS." Used since June 1, 1901.

88,175. **FINE AND BEAUTIFUL CUTTING.** THE SILVER GLOSS CO., Kansas, Ohio. Filed Mar. 12, 1902.

Essential feature.—A seal bearing a map of the State of Ohio with segments of bordering States and Lake Erie, the latter forming part of its northern boundary, together with underlying shores of grain. Used since April 1, 1902.

88,176. **ADmiral.** THE ADMIRAL ADmiral CO., Chicago, Ill. Filed Mar. 17, 1902.

ADMIRAL.

Essential feature.—The word "ADMIRAL." Used since December 15, 1902.

88,177. **FORNAGE MATERIALS.** HENRI L. LLOYD, London, England. Filed Mar. 21, 1902.

MORGANITE

Essential feature.—The word "MORGANITE." Used since January, 1902.

88,178. **STOVE, RANGE, HEATER, AND FURNACE.** BARKER BROTHERS & COMPANY, Chicago, Ill. Filed Mar. 9, 1902.

NATIONAL

Essential feature.—The word "NATIONAL." Used since March 1, 1902.

LABELS

REGISTERED APRIL 22, 1902.

8,085.—Title: "CAN'T SHAKE 'EM OFF." (For Eyeglasses.) HARRY H. WATTS, Kansas City, Mo. Filed February 7, 1902.

8,086.—Title: "SHOE MANUFACTURERS' SYNDICATE." (For Shoes.) WALTER BOWLETT, Boston, Mass. Filed March 22, 1902.

8,087.—Title: "BURNHAM'S SOLUBLE IODINE (THE ORIGINAL)." (For Soluble Iodine.) BURNHAM SOLUBLE IODINE CO., Boston, Mass. Filed March 22, 1902.

8,088.—Title: "MARSHALL'S DANDELION TONIC." (For a Medicine.) THOMAS P. MARSHALL, Atlanta, Ga. Filed March 21, 1902.

8,089.—Title: "BIG 4 COUGH AND COLD CURE." (For a Medicine.) J. CLARK BANTA, Pembina, Wis. Filed March 27, 1902.

8,090.—Title: "KELLER BROS. BLOOD PURIFYING REMEDY." (For a Medicine.) KELLER BROS., Newark, N. J. Filed March 2, 1902.

8,091.—Title: "FIG-FIZIC." (For a Laxative.) W. J. RAICHE, Marietta, Wis. Filed March 25, 1902.

8,092.—Title: "THE FAMOUS FILE CURE." (For a File Cure.) B. & W. Co., Fort Wayne, Ind. Filed February 27, 1902.

8,093.—Title: "VERMILION CLUB." (For Whisky.) BENJAMIN J. EUSTICE, Danville, Ill. Filed March 25, 1902.

8,094.—Title: "OLD STYLE LAGER." (For Lager-Beer.) G. HENKLEY BREWERY COMPANY, La Crosse, Wis. Filed March 27, 1902.

8,095.—Title: "ORANGE BREWERY BEER." (For Beer.) MICHAEL WINTER, Orange, N. J. Filed March 21, 1902.

8,096.—Title: "OSBURN'S POMELO PHOSPHATE." (For a Beverage.) FRANK LEE FULLER, Los Angeles, Cal. Filed April 1, 1902.

8,097.—Title: "BLACKBIRD." (For Lithia-Water.) ARLEN E. INGLEWATER, Clinton, Iowa. Filed March 17, 1902.

8,098.—Title: "FAULTLESS." (For Condensed Milk.) THE LACKAWANNA DAIRY CO., Scranton, Pa. Filed March 22, 1902.

8,099.—Title: "LA MOLINDA." (For Cigars.) HUNTER & GAMMEL, Chicago, Ill. Filed March 2, 1902.

8,100.—Title: "HOME INDUSTRY." (For Cigars.) SCHMIDT & CO., New York, N. Y. Filed March 20, 1902.

8,101.—Title: "NAILITKA OR GREASE EXTRACTOR." (For a Cleaning Preparation.) THEODORE H. PRINCE, New York, N. Y. Filed February 14, 1902.

8,102.—Title: "MELLIN'S FOOD CHOCOLATE." (For a Food Preparation.) MELLIN'S FOOD COMPANY OF NORTH AMERICA, Portland, Me., and Boston, Mass. Filed March 21, 1902.

DECISIONS

OF THE

COMMISSIONER OF PATENTS

AND OF

UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

EX PARTE BYRON WESTON COMPANY.

Decided March 2, 1902.

1. TRADE-MARKS — "DEFIANCE" — ARBITRARY, NOT GEOGRAPHICAL.

The word "Defiance" held registrable as a trade-mark for paper, since its geographical significance due to its use as the name of a town does not overshadow its original meaning of a challenge and take from it its arbitrary significance.

2. SAME — LONG USE — GEOGRAPHICAL SIGNIFICANCE AFTERWARD ACQUIRED.

Where a mark is arbitrary and distinctive when adopted, but has since become prominent geographically as the name of a place, held that in justice the applicant cannot be deprived of his mark unless its geographical significance is so great as to make it certain that it would be understood in that sense by the purchasing public.

On appeal.

TRADE-MARK FOR WRITING-PAPER.

Application for registration filed February 5, 1902, No. 65,062.

Messrs. Sturtevant & Greeley for the appellant.

ALLEN, Commissioner:

This is an appeal from the decision of the Examiner of Trade-Marks refusing to register the word "Defiance" as a trade-mark for writing-papers on the ground that it is geographical.

This mark was adopted as a trade-mark by Byron Weston in 1879 and was registered in this Office on April 16, 1878, No. 5,903. His successors in business, who have continued to use the mark, now seek to reregister it, and the principal ground of refusal is that the word has acquired a geographical meaning by use as the name of a place in Ohio. At the time when this mark was adopted and became the property of these parties as a trade-mark Defiance, Ohio, was not a place of importance and was so little known that the use of the word by these parties upon goods made at Dalton, Mass., had no geographical significance to the purchasing public and was understood only in its arbitrary and intended sense, meaning a challenge.

If a party can be deprived of his right to an arbitrary and distinctive mark acquired by actual use by the fact that it has since the date of that use become prominent geographically as the name of a place, it would seem that justice requires that the geographical significance of the word be so

great as to make it certain that it would be understood in that sense by the purchasing public when applied to goods. Doubts should be resolved in favor of the party using the mark.

The word "Defiance" in this case has the arbitrary significance of a challenge, and it is thought that it would be so understood even by that part of the purchasing public having a knowledge of Defiance, Ohio. The goods of these parties are not made at Defiance, Ohio, and that town has no reputation as the place of manufacture of paper. The geographical meaning of the word does not overshadow its original meaning and take from it its arbitrary significance as a trade-mark for paper.

The decision of the Examiner of Trade-Marks is reversed.

IN RE BACON.

Decided April 15, 1902.

INTERFERENCE — PRELIMINARY STATEMENT — SEALED AGAINST INSPECTION WHEN NOT USED.

Where the junior party's statement fails to overcome the filing date of the senior party, the preliminary statement of the senior party should remain sealed and should be placed in the confidential archives of the Office and should not be open to inspection either before or after the grant of the patent.

In the matter of the request of L. S. Bacon for copy of preliminary statement of Edwin S. Votey in interference file of *Whitehead v. Votey*.

ALLEN, Commissioner:

This is a petition by Mr. L. S. Bacon that he be permitted to obtain a copy of a preliminary statement filed by one Votey in the interference *Whitehead v. Votey*, No. 31,149.

In that interference *Whitehead's* preliminary statement failed to overcome Votey's filing date, and under the settled practice of the Office priority of invention was decided in favor of Votey without opening his statement, and under Rule 112 his unopened statement was removed from the interference file. This decision became final, and Votey's patent was issued on March 25, 1902, No. 653,312.

The petitioner contends that Votey's patent having issued, all papers relating to it, including the preliminary statement, should be open to public inspection. This contention is sound in so far as papers which were considered in determining whether or not that patent should be granted are concerned; but the preliminary statement stands

upon a different footing, since it was never opened or considered. No action was based upon that statement, and it was not necessary for Votey to have filed it. In so far as the consideration of his application was concerned it might have been at once returned to Votey unopened, and it would have been except for the general policy of the Office to retain all papers filed. (*Ex parte Baxter*, 56 O. G., 1448.)

In filing his statement Votey may have relied upon the settled practice of the Office, which protects him from publicity in case consideration of his statement is found unnecessary, (*Lindsey v. McDonough*, 55 O. G., 1402,) and therefore it would be unfair to him to change that practice without good reason therefor. No good reason is seen for changing it. There is no more reason for permitting the general public to see the statement after the patent is granted than there is for permitting the opposing party to the interference to see it before the grant. The reason for refusal is that the statement constitutes no part of the proceedings leading to the grant of the patent.

It is held that where the junior party's statement fails to overcome the filing date of the senior party the statement of the senior party should be placed in the confidential archives of the Office and should not be open to inspection either before or after the grant of the patent.

The petition is denied.

EX PARTE FOX AND BARRETT.

Decided April 15, 1902.

1. DIVISION—PARTS OF TYPE-WRITER CARRIAGE.

Division properly required between parts of a type-writer carriage, since it appears that the various devices have acquired a distinct status in the art and are separate subjects of manufacture and sale.

2. SAME—CLASSIFICATION.

The mere fact that inventions would be separately classified in this Office is not in itself sufficient to warrant a requirement for division; but in the present case the classification has followed the lines established by inventors and manufacturers and is evidence of the fact that the devices have acquired such a distinct status in the art as warrants not only such separate classification, but also separate applications for invention included therein.

ON petition.

Application of William R. Fox and Glenn J. Barrett filed December 11, 1901, No. 85,432.

Mr. Fred. L. Chappell for the applicants.

ALLEN, Commissioner:

This is a petition from the action of the Examiner requiring division between the claims of the above-entitled application.

The claims, in the opinion of the Examiner, cover the following independent inventions: claims 9, 10, and 11, a carriage-feed mechanism; claims 14 to 20, inclusive, a carriage-stop mechanism; claims 24 to 26, inclusive, a line-spacing mechanism; claims 53 to 67, inclusive, and claims 69 to 73, inclusive, a paper-feed mechanism; claims 68, 75, 76, 77, a scale and pointer mechanism. The remaining claims

(Vol. 99, No. 4.)

relate to parts of the carriage mechanism not separately classified.

The devices covered by the groups of claims enumerated above relate to the carriage of a type-writing machine. The claims of the first group—claims 9, 10, and 11—cover an escapement mechanism, by means of which the carriage is advanced step by step during the printing operation. Those of the second group—claims 14 to 20, inclusive—relate to stop devices, by means of which the advance of the carriage through the operation of the escapement device may be stopped at a predetermined point. The claims of the third group—claims 24 to 26, inclusive—relate to a spacing mechanism, by means of which the proper spacing between the lines is made. This mechanism comprises a ratchet-head mounted on the platen and means for turning the parts as desired. Claims 53 to 67 and 69 to 73, forming the fourth group, cover devices for feeding the paper to the platen and holding it in place thereon. The claims of the fifth group cover indicating devices, by means of which the point at which the printing is to be done may be ascertained. All these devices are connected in some way with the operation of the carriage; but it is clear that the various functions effected by them are independent. For example, the operation of the line-spacing mechanism is not in any way affected by the presence or absence of the carriage-stop mechanism; nor is the carriage-feed dependent upon the scale and pointer. Furthermore, these various devices are separate subjects of invention, as is shown by the numerous patents contained in the subclasses referred to by the Examiner, and it appears that they are to some extent separate subjects of manufacture and sale. Under these circumstances it is well settled that division should be required. (*Ex parte Smith*, 98 O. G., 1971; *ex parte Sturtevant and Sturtevant*, 98 O. G., 1971.)

It is contended by applicant that division should not be required, because this application was filed prior to the establishment of the classification containing the subclasses in which the inventions embraced by this case will be placed. This, however, is not a valid reason for setting aside the requirement. The mere fact that inventions would be separately classified in this Office is not in itself sufficient to warrant a requirement for division; but in the present case the classification has followed the lines established by inventors and manufacturers and is evidence of the fact that the devices have acquired such a distinct status in the art as warrants not only such separate classification, but also separate applications for inventions included therein.

The petition is denied.

BERRY & FITZSIMMONS.

Decided April 15, 1902.

INTERFERENCE—MOTION TO AMEND—BURDEN—APPEAL LIES FIRST TO THE EXAMINER-IN-CHIEF—PRACTICE.

Where a motion is made by one party to an interference to amend his application under the provisions of Rule 109 and the Examiner denies said motion on the ground that the moving party has no right to make the claim, held that said decision involves a question of merits and an appeal therefrom lies in the first instance to the Examiner-in-Chief.

APPEAL ON MOTION.

BOOKING—ORIGINAL.

Application of James D. Berry filed August 5, 1899, No. 723,842. Application of Philip Fitzsimmons filed June 28, 1899, No. 72,189.

Mr. H. A. Toumin and Mr. L. S. Bacon for Berry. Mr. James N. Ramsey for Fitzsimmons.

ALLEN, Commissioner:

This is an appeal by Fitzsimmons from the decision of the Primary Examiner denying his motion brought under the provisions of Rule 109 to amend his application involved in the above-entitled interference by inserting therein two claims corresponding to claims 1 and 2 of the Berry application, which claims have been adjudged to be patentable to Berry.

The Examiner denied the motion on the ground that in his opinion "Fitzsimmons has no right to make the claims presented by this motion," giving as a reason for this opinion that the disclosure in the Fitzsimmons application does not warrant the allowance to Fitzsimmons of the claims in question, and from his denial this appeal is taken.

Rule 109 provides that—

When an application is involved in an interference in part and shows and describes, without claiming a patentable invention, . . . the applicant may . . . file an amendment of his application duly claiming such invention.

It further provides that—

The decision of the Primary Examiner will be binding upon the Examiner of Interference, unless reversed or modified on appeal, as provided in Rule 134.

This latter rule excepts out of the class of appeals which may be taken directly to the Commissioner those—

2. On motions involving the merits of the invention. Decisions on these motions, when appealable, go to the Examiner-in-Chief, in the first instance.

The question of merits is defined under Rule 133, and its application to this case is in that part of said rule which is expressed in the terms—

. . . for want of identity with the invention previously disclosed, or because the circumstances involve a departure from the invention originally presented.

In the present case it is clear that this appeal has been brought to the wrong tribunal, and is for this reason dismissed; but with permission to take an appeal to the Examiner-in-Chief within ten days from the date hereof.

EX PARTE SHONE.

Decided April 15, 1902.

1. PETITION TO COMMISSIONER—QUESTIONS MUST BE TWICE ACTED UPON.

A petition should not be brought until the case has been twice acted upon with reference to the point involved in the petition. (Rule 141.) (*Ex parte Hong*, 97 O. G., 192.)

2. SAME—SAME.

A petition taken to the Commissioner from the first action of an Examiner held to be premature and inadvisable.

3. SAME—SAME—REASONS FOR WITHDRAWING COMMISSIONER MUST BE STATED.

Petitions taken without a request for reconsideration accompanied by a statement of reasons why the objection should be withdrawn which will inform the Examiner of the applicant's position place much unnecessary labor on the Commissioner and cause delay.

ON petition.

ONE-CONTROLLED SHOOTING-GALLERIES.

Application of James W. Shone filed January 9, 1901, No. 43,640.

Mr. Frederick F. Church for the applicant.

ALLEN, Commissioner:

This is a petition from the action of the Examiner refusing to enter and consider a certain amendment filed February 12, 1902, to the above-entitled application and holding the application to be abandoned for lack of such proper prosecution as the condition of the case required.

It is therefore prayed:

(a) That the Examiner in charge of said application be advised that the amendment of February 12, 1902, be entered in the case.
(b) That the case be reinstated and an action be had on the merits of the claims in the same manner as if said amendment had been properly entered by the Examiner upon the date of its receipt.

The records show that the Examiner made an action requiring division between certain of the claims on February 12, 1901.

On February 12, 1902, the petitioner filed an amendment which, in his opinion, was responsive to the Office action.

On March 1, 1902, the Examiner informed the petitioner that the amendment was, in his opinion, not fully responsive to the last Office action and refused to enter the same on the ground that such entry would only necessitate another requirement of division. The petitioner was further informed in this letter of March 1, 1902, that—

as more than a year has elapsed since the last preceding Office action without an appropriate action on the part of the applicant, the case is abandoned.

On March 25, 1902, this petition was taken. No request, accompanied by reasons therefor, was made of the Examiner for a reconsideration of his action of March 1, 1902, and consequently no reconsideration by the Examiner of his first action was possible. Rule 145 provides in part as follows:

Upon receiving a petition stating concisely and clearly any proper question which has been twice acted upon by the Examiner, and which does not involve the merits of the invention claimed, . . . an order will be made fixing a time for hearing such petition by the Commissioner.

It is therefore seen that one of the requirements of the rule which warrants the taking of a petition from an action of the Examiner to the Commissioner is that the question for decision must have been twice acted upon by the Examiner. So long as the rule is in force it should be strictly followed. The provisions of the rule are explicitly stated, and they are based upon reason. If the practice permitted a petition to be taken after the first action of an Examiner, not only much unnecessary labor would be placed upon the Commissioner, but also the prosecution of the application before this Office would be unnecessarily delayed. It is as essential that the formal questions on which petitions are taken should be twice acted upon as it is that questions involving the merits should be twice acted upon (section 499 of the Revised Statutes) before appeals from the decisions of the Primary Examiner are taken to the Examiner-in-Chief.

Rule 67 provides for a reconsideration by the Examiner of his action on "preliminary or interme-

[Vol. 99, No. 4.]

diate" questions; but in order to be entitled to the reconsideration the applicant must under the provisions of Rule 60 "make request therefor in writing, and he must distinctly and specifically point out the supposed error in the Examiner's action." By following this practice many questions can be settled by the Examiner and no petition would be necessary.

In *ex parte Appel*, (84 O. G., 1145.) though the facts were in some respects different, the principle was the same as in this case. In this decision it was stated:

Arguments are presented upon the petition which should have been presented to the Examiner. To expect that they will be here considered is in effect to expect the Commissioner to act upon the case in the first instance. This is not his duty. Proper practice requires that the applicant should, through his attorney, present fully before the Examiner, the reasons why objections made should be withdrawn, and only after the position taken by the applicant is made clear to the Examiner should petition be taken.

As stated in *ex parte Haug*, (97 O. G., 199):

"A petition should not be brought until the case has been twice acted upon with reference to the point involved in the petition. (Rule 145.)"

This petition, being prematurely brought, is dismissed.

DECISIONS OF THE U. S. COURTS.

Court of Appeals of the District of Columbia.

THOMSON v. WESTON.

Decided March 1, 1903.

1. INTERFERENCE—PRIORITY—PRIVATE USE OF INVENTION.

Where T. made an electric measuring instrument embodying the invention in controversy in 1894 and placed it in his private experimental room, where it was seen only by employees, but where it was used frequently in making measurements, and T. did not manufacture it or apply for a patent until 1898, after he knew of W.'s patent upon it, Held that W. is entitled to the decision on priority. (*Citing Mason v. Hepburn*.)

2. SAME—DELIBERATE CONCEALMENT OF INVENTION—FORFEITURE OF RIGHTS IN FAVOR OF ONE LATER.

Where a party deliberately conceals his invention after completion without reasonable excuse and is stimulated to make application for a patent only by the publication of a patent to another and later inventor, Held that he has forfeited his rights in favor of the later and more diligent inventor and that the length of the concealment is not material.

3. SAME—SAME—SAME.

By deliberate concealment or suppression of the knowledge of his invention the inventor subordinates his claim, in accordance with the general policy of the law in the promotion of the public interest, to that of another and bona fide inventor who during the period of inaction and concealment shall have given the benefit of the discovery to the public.

4. SAME—EXPERIMENTAL DEVICE—LONG DELAY AFTER TEST AS EVIDENCE.

The circumstances of private and partial test accompanied by long delay thereafter have justly been given great weight as indicating with certainty that the device was experimental merely and not satisfactory.

Mr. Albert G. Davis for the appellant.

Mr. Chas. J. Kintner and Mr. Marcellus Bailey for the appellee.

SHEPARD, J.:

This is an interference proceeding the issue of which was defined in three counts as follows:

1. Two electric measuring instruments attached to a single or common base and having their indicating needles so located with relation to a scale-plate that independent readings may be taken at the same instant.

2. Two electric measuring instruments attached to a single or

common base, in combination with a dial-plate provided with scales for the index-needles of both instruments.

3. Two electric measuring instruments each provided with an index needle operatively connected with the rotary or movable part of its own instrument, said rotary or movable parts being located in the magnetic fields between the opposite ends of a pair of energizing magnets.

The voltmeter, for measuring the electromotive force or pressure of an electric circuit, and the ammeter, for measuring the quantity of passing current in such circuit, were well-known devices at the time of the invention of the issue, but had not been combined in a single instrument.

The terms of counts 1 and 2 are directed to what is known as the duplex instrument, containing both a voltmeter and an ammeter so arranged in relation to each other that their respective index-needles move on the same dial-plate and show their respective measurements at the same time.

This capacity for simultaneous observation of the pressure, or voltage, and of the quantity of passing current, makes the instrument a desirable part of the equipment of an ordinary electric automobile.

Count 3 relates to the employment of the duplex instrument of a pair of magnets common to the moving parts of both measuring devices, instead of separate and independent magnets for each.

The appellee, Weston, holds a patent that was issued March 23, 1898, on an application filed December 7, 1897. Since the date of his invention he has manufactured and put in commercial use a great number of his duplex instruments.

The appellant, Thomson, filed his application June 21, 1898.

The tribunals of the Patent Office all agreed that Weston was clearly entitled to priority of invention as regards counts 1 and 2, and those decisions have been acquiesced in by Thomson. The controversy, therefore, involves count 3 alone.

As to this, the Examiner of Interferences awarded priority to Thomson; but expressed the opinion that he was not entitled to a patent because of his concealment of the invention from the public, and called the attention of the Commissioner thereto under the provisions of Rule 124.

The Examiners-in-Chief—one not taking part in the decision—affirmed the decision, but did not join in the recommendation that patent be denied to Thomson on account of delay and concealment.

The Commissioner of Patents, on appeal, reversed that decision and awarded priority to Weston.

All the tribunals of the Patent Office agree, substantially, that Weston conceived and disclosed the invention of count 3 about November 23, 1896, and reduced it to practice on October 21, 1897.

Thomson alleged conception about the last week of June, 1894, at which time he made sketches, explained the invention to an assistant and instructed him to make an instrument in accordance therewith; that a full-sized working device was made during July and August, 1894, and was, prior to September, tested and calibrated in the instrument-room of the General Electric Company at Lynn, Mass.; and that it has been used since said time for the purpose of testing electrical apparatus.

Thomson is a skilled electrician and inventor of electrical measuring instruments. For these he has eight patents—the first three on applications filed October 26, 1894, and the latest on March 27, 1897.

Testifying as a witness in regard to this invention, he said that he had completed a form of voltmeter called an "astatic voltmeter," in May, 1894; that he undertook to apply this construction to an ammeter in June thereafter; that he then conceived the idea of combining the two in one instrument; that it was in his mind with particular reference to a private lighting plant then in use in his own house and which he proposed to remodel; that he desired to use the instrument to keep informed both in respect of the pressure and the quantity of the current in said plant; that he mentioned it to his assistant, Shand, gave him some instructions and directed the construction of the instrument suggested; that, returning from his vacation, August 6, 1894, he found the instrument completed; that it was a working instrument and was mounted on a switchboard in his model-room and used frequently in making measurements. It appears from the testimony that this model-room is the private workshop of Thomson; that it is not an exhibition-room and that the public are excluded from it; that it is accessible to his assistants, and mechanics employed in the works frequently came into it for tools, etc. It was said also, that while there was a posted notice against admittance, Mr. Thomson was not rigid in its enforcement. It is not made to appear that any one but assistants and mechanical employees ever saw or heard of the instrument, and Thomson could remember no one but his assistant Shand using the instrument. It was not applied to, or used in, the private electric plant before mentioned.

In explanation of his failure to apply for a patent, or to manufacture the instrument, Thomson said that he was engaged in looking after the patenting of a voltmeter and ammeter separately and had a great deal of patent-work on hand; that his attention was not called specially to this instrument as a subject for patent, and being doubtful of its patentability he took no steps to that end until after he had seen the notice of the issue of the patent to Weston; then he wrote to the patent department of the General Electric Company at Schenectady, N. Y., calling attention to the Weston patent issue and referring to his instrument in a general way.

Robert Shand, the assistant before mentioned, corroborated Thomson in the matter of description and order for construction of the machine in the summer of 1894. He said that he had one Charles Silvester, a mechanic, to work on the instrument in June and when made he took it to the instrument-room where it was calibrated under charge of one Holden; that it was then taken to Thomson's private mechanical laboratory, and certain defects were remedied; that it has been in continuous use in that room since about the first of September.

Silvester identified the instrument as the one

worked on by him and that had been kept in a switchboard in Thomson's laboratory and used since September, 1894.

Jameson, another mechanic, testified to the construction of the instrument in the summer of 1894.

On behalf of Weston, a vigorous attack is made upon the sufficiency of this evidence to show conception and reduction to practice, under the burden of proof imposed upon Thomson not only by the prior patent of his rival, but also by his long inaction and delay.

That the instrument, which was produced during the taking of the testimony, was in fact constructed, as claimed, there can be no reasonable doubt. Whatever of doubt there may be, as affecting Thomson's claim, would seem to relate exclusively to the point of actual, successful reduction to practice. The question involves something of matter of opinion as well as of matter of fact. It is this: Whether, considering the failure to bring the instrument into use either in the private plant for which it was originally designed, or in connection with any other practical construction, as well as the delay in applying for a patent by an inventor and a manufacturer engaged in patenting and utilizing, generally, all inventions in this art, the test in the private laboratory of the inventor failed to demonstrate the practical utility of the machine, as then adjusted, and caused it to be regarded and abandoned as an experiment, for the time at least.

It is quite true, as contended by the appellee, that great stress has frequently and justly been laid upon circumstances of private and partial test and long delay thereafter, as indicating, with certainty, nothing more than an unsatisfactory, experimental use, when subsequently brought forward to overcome the patent of a diligent inventor in the same field who has not only given the benefit of his discovery to the public through the Patent Office, but also through manufacture and general introduction into commercial use. (*Treuer v. Brown*, 34 O. G., 311; 14 App. D. C., 24; *Warner v. Smith*, 18 App. D. C., 111, 113; *Appert v. Schmertz*, 36 O. G., 1824; 18 App. D. C., 117, 120; *Fafel v. Stocker*, 34 O. G., 433; 17 App. D. C., 317, 321; *Reichenbach v. Kelly*, 34 O. G., 1185; 17 App. D. C., 333, 344; *Latham v. Armat*, 35 O. G., 332; 17 App. D. C., 345, 353.)

This question—whether the evidence, in the light of all the attendant circumstances, was sufficiently strong to establish, beyond doubt, the fact of actual reduction to practice, under the rule applied in the cases cited, need not now be determined.

The Commissioner expressly waived it and, assuming the fact of reduction to practice, denied priority to Thomson upon another and distinct ground.

Concurring in his conclusion upon that ground, we will follow the course pursued in his decision.

That conclusion is, that Weston, although later than Thomson in conception and reduction to practice, is nevertheless an inventor and entitled, as such, to an award of priority because of the de-

liberate concealment by Thomson, from the public, of all knowledge of his invention and use.

The facts relating to the action of Thomson are fairly summarized by the Commissioner as follows:

After Thomson made his instrument in 1894 he placed it in his model-room, or private laboratory, to which outsiders were not admitted, and this instrument was only seen by the employees who might go into that room, and the knowledge of this instrument and its use in the model-room was confined to Thomson and his assistant, Shand.

The use to which Thomson put this device, whatever it may have been, was in his private model-room. The public was not made acquainted with the instrument or its use and derived no benefit whatever from it. It seems that he did not attach sufficient importance to it to take steps to obtain a patent, and he believed that it was not patentable. He deliberately concealed the invention from the public until another had patented the device and put it into extensive use.

As held by the Commissioner, the foregoing facts bring the case directly within the operation of the doctrine enounced in *Mason v. Hepburn*, (84 O. G., 147; 18 App. D. C., 98.)

In that case it appeared that Mason had conceived the idea of the gun-clip in controversy, had made it and applied it to a completely finished gun, and that the gun had then been put away in the model-room of the Winchester Arms Company, which employed Mason and was entitled to the benefit of his inventions. The gun was probably tested in the shooting-gallery of the company.

Knowledge of these facts was confined to the inventor and a few other employees of the company who had access to the model-room. Further test of the clip, than as stated above, was treated as immaterial; in fact what was done was regarded as answering the substantial requirements of the law in respect of the reduction to practice of such a device.

What was then said of the effect of that action is directly applicable to the facts under consideration in the present case:

Although the construction and adaptation to use of the clip were within the knowledge of several persons, these were all, with Mason himself, employees of the Winchester Repeating Arms Company, for whose benefit the invention was made. They had either been called on to aid in the construction and use, or by the nature of their employment, were necessarily cognizant of it. The invention was therefore as much secreted from the public as if it had been confined to the knowledge of Mason alone. (*Peacock v. Dialogue*, 1 Pet., 1, 19; *Kendall v. Winsor*, 31 How., 323.) The public did not, and was not intended to receive any benefit from it during the seven years that intervened between the construction and the application for the patent. (18 App. D. C., p. 91.)

It is true that the time of concealment in this case was something less than four years as against seven years in that. The mere difference in time, however, is not sufficient to affect the application of the principle, for it is as certain in one case as in the other that the application for the patent was solely stimulated by the publication of the patent granted to another inventor. No substantial or even plausible excuse for Thomson's inaction is disclosed by the testimony.

Again in *Mason v. Hepburn*, after quoting the statement of the "true policy and ends of the patent laws," made in *Kendall v. Winsor*, (31 How., 323, 327,) it was said:

Considering, then, this paramount interest of the public in its bearing upon the question as presented here, we think it impera-

tly demands that a subsequent inventor of a new and useful manufacture or improvement who has diligently pursued his labors to the procurement of a patent in good faith and without any knowledge of the preceding discoveries of another, shall, as against that other, who has deliberately concealed the knowledge of his invention from the public, be regarded as the real inventor and as such entitled to his reward. (Id., p. 98.)

In support of this proposition, many decisions of the courts and of Patent Commissioners were cited. Since then the practice of the Patent Office has been governed by the rule as declared and the principle has been reasserted by us in several decisions. (*Warner v. Smith*, 84 O. G., 311; 13 App. D. C., 111, 115; *Esty v. Newton*, 86 O. G., 799; 14 App. D. C., 50, 53; *in re Mower*, 88 O. G., 191; 15 App. D. C., 144; *McBerty v. Cook*, 90 O. G., 2305; 16 App. D. C., 123, 129; *Fescl v. Stocker*, 94 O. G., 423; 17 App. D. C., 317, 323; *Reichenbach v. Kelly*, 94 O. G., 1185; 17 App. D. C., 333, 343.)

It is true that in the majority of the above cases the decisions went upon another ground, but the principle was involved and was restated, and may be regarded as settled as far as it can be by this court.

What was said in *McBerty v. Cook*, *supra*, and has been referred to on behalf of the appellant, namely, that "the rule will not be extended to any case not coming clearly within it," was not to impair its force but to recall attention to the restricted field of its application.

The particular object of the beneficence of the patent law is the individual who first conceives, and with diligence perfects an invention. And where one has completed the act of invention his right to the reward in the form of a patent becomes complete save in two instances that may be satisfactorily shown to exist. First, he loses the right as against the public in general by a public use for the statutory period. Second, by deliberate concealment or suppression of the knowledge of his invention he subordinates his claim, in accordance with the general policy of the law in the promotion of the public interest, to that of another and bona fide inventor who during the period of inaction and concealment shall have given the benefit of the discovery to the public. Viewed in the light of "the true policy and ends of the patent laws," the latter is the first to invent, and therefore entitled to the reward. As said in *Mason v. Hepburn*:

The true ground of the doctrine, we apprehend, lies in the policy and spirit of the patent laws and in the nature of the equity that arises in favor of him who gives the public the benefit of the knowledge of his invention, who expends his time, labor and money in discovering, perfecting and patenting, in perfect good faith, that which he and all others have been led to believe had never been discovered, by reason of the indifference, supineness or wilful act of one who may, in fact, have discovered it long before.

The concealment of the appellant in this case having been deliberate and without reasonable excuse, the Commissioner was right in awarding priority to his opponent, and his decision will be affirmed. It is so ordered, and that the clerk certify this decision and the proceedings herein to the Commissioner of Patents as provided by law.

Change in Classification.

(Order No. 1,462.)

DEPARTMENT OF THE INTERIOR.

UNITED STATES PATENT OFFICE,

Washington, D. C., April 17, 1902.

It is directed that subclass III, Magnetic, of class III, Electricity, Division VII, be abolished, the patents therein having been transferred to subclass IIIA, Transmission of power, direct, in class III, Electricity, Motive Power, in Division XXVI.

F. L. ALLEN,

Commissioner.

Revision of Trade-Mark Rules.

(Order No. 1,461.)

DEPARTMENT OF THE INTERIOR.

UNITED STATES PATENT OFFICE,

Washington, D. C., April 8, 1902.

Rule 21, subdivision (b), governing the registration of trade marks, is hereby amended to read as follows:

(b) A statement specifying name, domicile, location, and citizenship of the party applying; the class of merchandise and the particular description of goods comprised in such class to which the particular trade-mark has been appropriated; a description of the trade-mark itself, and a statement of the mode in which the same is applied and affixed to goods, and the length of time during which the trade-mark has been used, and if the applicant be a corporation it must set forth under the laws of what State or nation incorporated.

F. L. ALLEN,

Commissioner.

Amendment of Section 4833, Revised Statutes, Relating to the Signing of Letters Patent.

DEPARTMENT OF THE INTERIOR,

UNITED STATES PATENT OFFICE,

Washington, D. C., April 12, 1902.

By the act approved April 11, 1902, section 4833, Revised Statutes, has been amended to read as follows:

SEC. 4833. All patents shall be issued in the name of the United States of America, under the seal of the Patent Office, and shall be signed by the Commissioner of Patents, and they shall be recorded, together with the specifications, in the Patent Office in books to be kept for that purpose.

F. I. ALLEN,
Commissioner.

Attorneys.

DEPARTMENT OF THE INTERIOR,

UNITED STATES PATENT OFFICE,

Washington, D. C., April 26, 1902.

This Office has been advised of the disbarment by the Secretary of the Interior of the following attorney from practice before the Department or any Bureau thereof: John M. Carver, Canton, N. C.

C. M. IRELAND,
Chief Clerk.

PATENTS

GRANTED APRIL 29, 1902.

698,496. ABDOMINAL BANDAGE. EUGENE L. ARDREY, New York, N. Y. Filed Mar. 1, 1901. Serial No. 66,412. (No model.)

Claim.—1. An appliance of the class herein described comprising a protective and supporting member, as 2, composed of a plurality of superimposed layers of flexible material, the front layer thereof being provided with a series of suitably spaced openings; stud-like fasteners projecting outwardly through each one of said openings; a universally-flexible leader loosely interposed between adjoining layers of said member and connectively connecting said stud-like fasteners by being coiled around each of them and upon itself, each of said fasteners being adapted to firmly engage the leader and accordingly resist detachment from said member; and means for retaining said member in position for service at the abdomen of the user.

2. An appliance of the class herein described comprising a protective and supporting member, as 2, composed of a plurality of superimposed layers of flexible material, the front layer thereof being provided with a series of suitably spaced openings; stud-like fasteners projecting outwardly through each one of said openings; a universally-flexible leader loosely interposed between adjoining layers of said member, the said leader connectively connecting said fasteners by being coiled around each of them and upon itself; means for adjustably connecting the ends of said leader and whereby the latter may be adjusted as to length, each of the fasteners being adapted to firmly engage the leader and accordingly resist detachment from said member; and means for retaining said member in position for service at the abdomen of the user.

698,497. GAS-LIGHTER. EDWARD B. ARNOLD, New York, N. Y. Filed July 2, 1901. Serial No. 66,394. (No model.)

Claim.—1. A lighting attachment for gas-burners comprising a body arranged to enclose the burner, an apertured cap at the upper end of said body, the cap and body forming together a shoulder to limit the downward movement of the attachment, and a lighting substance carried by said attachment.

2. A lighting attachment for gas-burners comprising a body arranged to enclose the burner, a spring-tongue arranged at the opposite side to the said body, a cap connected with the upper ends of the body and of the tongue, said cap being apertured for the passage of gas and a lighting substance carried by the attachment.

3. In a gas-lighter, the combination of the supporting-body with a spiral having its inner end extended outwardly beyond the cells hang-

wire of the body and fastened thereto, the cells being arranged in front of said end, and a lighting substance carried by the outer end of the spiral.

4. In a gas-lighting attachment for burners the combination of a slitted cap and means for attaching it to the burner with a spiral secured to said cap, a lighting substance carried by the spiral and a stop to limit the movement of that part of the spiral which carries the lighting substance.

5. In a gas-lighter, the combination of the supporting-body having portions bent outwardly to form straps, with a spiral having its inner end extended through said straps and its cells arranged in front of said inner end, and a lighting substance carried by the outer end of the spiral.

698,498. PAPER OR PULP-BOARD MAKING MACHINE. LEONARD ARNOLD, Philadelphia, Pa. Filed Nov. 27, 1900. Serial No. 734,681. (No model.)

Claim.—1. The combination in a pulp-board or paper making machine, a roll upon which the paper or paper-pulp is laid, a pivoted outer-blade, means for actuating the said outer-blade to throw it toward and from said roll, means for feeding the cut paper or pulp away from the outer-blade, comprising a pivoted frame, a counterbalance for said frame, and a lay-boy pivoted to said frame for transferring the sheets from the same, said lay-boy being so pivoted with the frame that its contact with the deposited sheets will tend to lift the frame and permit a partial raising of the same by the weight of the counterbalance.

2. The combination in a paper or pulp-board making machine, of a roll upon which the pulp is laid, a pivoted outer-blade extending the length of said roll and adapted to cover the pulp laid thereon, an arm carried by said outer-blade a spring connected to said outer-blade and tending to

these it against the roll, a cam contacting with the arm of the outer-blade whereby the latter is held away from the roll, said cam having a depression for the reception of the end of the outer-blade arm thereby permitting movement of said outer-blade at regular intervals, means for feeding the sheet of pulp away from the roll to a frame or feed-table, and a series of lay-bands pivoted to said frame for transferring the sheet therefrom, substantially as described.

698,499. DIPPING-TANK FOR PHOTOGRAPHIC DUPLICATION PROCESS. JONAS W. AYLWORTH, East Orange, and WALTER E. HILLMAN, Orange, N. J., assignors to National Photograph Company, Orange, N. J., a Corporation of New Jersey. Filed May 2, 1901. Serial No. 64,421. (No model.)

Claim.—1. An improved tank for a photographic duplication process, comprising a receptacle or vessel for containing a molten coagulable material, a down-flow-passage in said vessel, an up-flow-passage therein, said passages being connected at the top and bottom, whereby the molten material may flow down the down-flow-passage to and up through the up-flow-passage and across to the down-flow-passage, so that a cross circulation of the material in its upper strata and a reverse circulation of the material in its lower strata will be secured, means for effecting the flow of such material, and means for heating the material, substantially as set forth.

2. An improved dipping-tank for a photographic duplication process, comprising a vessel or receptacle for containing a molten coagulable material, two vertically-arranged partitions in said vessel forming a down-flow-passage, an up-flow-passage, and a centrally-arranged dipping-space, the down-flow-passage being connected with the up-flow-passage substantially as set forth, means for maintaining a circulation of material in the vessel, and means for heating the material.

3. An improved dipping-tank for a photographic duplication process, comprising a vessel or receptacle for containing the molten coagulable material, two perforated circulating-pipes in the vessel, means for drawing material downwardly into one of said pipes and for forcing the material upwardly from the other of said pipes, and a connection between said pipes, substantially as set forth.

4. An improved dipping-tank for a photographic duplication process, comprising a vessel or receptacle for containing the molten coagulable material, two perforated circulating-pipes in the vessel, means for drawing material downwardly into one of said pipes and for forcing the material upwardly from the other of said pipes, a connecting circulating-pipe between the two, and means therein for maintaining circulation, substantially as set forth.

5. An improved dipping-tank for a photographic duplication process, comprising a vessel or receptacle for containing the molten coagulable material, two perforated circulating-pipes in the vessel, means for drawing

material downwardly into one of said pipes and for forcing the material upwardly from the other of said pipes, a connecting circulating-pipe between the two, and a worm therein for maintaining circulation, substantially as set forth.

6. An improved dipping-tank for a photographic duplication process, comprising a vessel or receptacle, means for heating the molten material, means for maintaining the molten material in circulation, and even partitions or diaphragms within the tank for guiding the cross circulation of the material, substantially as set forth.

7. An improved dipping-tank for a photographic duplication process, comprising a vessel or receptacle, means for heating the molten material, means for maintaining the molten material in circulation, even partitions or diaphragms within the tank for guiding the cross circulation of the material, and longitudinal partitions in said vessel or receptacle, substantially as set forth.

8. An improved dipping-tank for a photographic duplication process, comprising a vessel or receptacle, three connected circulating-pipes therein, the outside pipes being perforated, and means in the middle pipe for maintaining a circulation through the same, substantially as set forth.

9. An improved dipping-tank for a photographic duplication process, comprising a vessel or receptacle, three connected circulating-pipes therein, the outside pipes being perforated, and a worm in the middle pipe for maintaining a circulation, substantially as set forth.

10. An improved dipping-tank for a photographic duplication process, comprising a vessel or receptacle, three connected circulating-pipes therein, the outside pipes being perforated, means in the middle pipe for maintaining a circulation through the same, and means for adjusting the width of the slots in said pipes, substantially as set forth.

698,480. SCREW-PLATE. WILLIAM J. BAKER, Cleveland, Ohio. Filed Jan. 11, 1901. Serial No. 63,898. (No model.)

Claim.—1. In a screw-plate the combination with the stock; of a die relatively fixed; a complementary die having a reciprocating movement longitudinally of the stock; and a cam mechanism for positively moving said complementary die in both directions, said die in its inner position being automatically held locked against outward movement under pressure, due to the major axis of the cam crossing the point against which the pressure is applied, the movement being limited.

2. In a screw-plate the combination with the stock thereof, of a fixed and a transversely-slotted die, the latter having a reciprocating movement longitudinally of the stock; and a handle-operated eccentric located within a slot of the last-named die, in pivotal connection with a clamping-rod, said eccentric moving said die in both directions and preventing an outward movement of the movable die under pressure when said die is moved to its inner position.

3. In a screw-plate, the combination with the stock; of a die relatively fixed; a complementary die having a reciprocating movement longitudinally of the stock, said die having a transverse slot; and an eccentric extending into said slot and adapted to impart movement to the die in both directions, said slot and eccentric having a relative co-operation to automatically hold said die locked against outward pressure when said die is in its inner position.

698,481. TWYER. SAMUEL E. RICHMOND, Washington, D. C., assignor to Howard Evans, Philadelphia, Pa. Filed Oct. 6, 1900. Re-noved Jan. 27, 1902. Serial No. 91,515. (No model.)

Claim.—1. The combination with the circular frame of a converter, having a plurality of holes therein, of a corresponding number of twyers, one for each hole, said twyers vertically adjustable from their inner ends

as centers whereby an all-around blast of air may be directed at varying angles at a level approximately coincident with the horizontal plane in which the holes are located.

2. The combination with a twyer ring or frame having openings formed therein at intervals and provided with radially-disposed hollow projection adjacent to these openings and a wind-box in communication with and for applying air to the projections, of twyers extending into the openings in the ring or frame, said twyers having hollow bores which open into the sides of the twyers and communicate with the hollow projections, and means for adjusting the twyer.

3. The combination with a frame having openings formed therein, and hollow projections each having a flat face in alignment with one side of each opening, of a twyer extending into each opening and provided with a flat surface adapted to fit the flat surface of the projection, the twyer and the projection having openings therein in communication with each other.

4. The combination with a frame having openings formed therein and hollow projections adjacent to each of said openings one face of each projection flat and in alignment with one of the openings, these flat faces of the projections each provided with an elongated outlet, of a twyer extending into each opening, the hollow bores of the twyers opening into the elongated outlets in the projections, whereby the two are maintained in constant communication regardless of the position of the twyer.

5. The combination with a frame having a plurality of holes therein and hollow projections adjacent to the holes, of twyers having their hollow bores in constant communication with the hollow projections, said twyers each having a segmental slot formed therein and means extending through said slots into the projections for regulating the movement of twyers and covering them in various adjustments.

6. The combination with a wind-box and hollow projections, the latter of which are in communication with said wind-box and provided with curved elongated outlets, of twyers each of which is provided with a segment and a handle, said segments having segmental elongated slots, and bolts or set-screws passing through said slots into the hollow projections for securing the twyers adjustably in position, the curved outlets in these hollow projections maintaining constant communication with the twyers.

698,482. INCANDESCENT GAS-BURNER. JAMES W. BAKER, Bradford, England, assignor of two-thirds to William George Stansfeld, Bradford, England. Filed Sept. 9, 1901. Serial No. 74,005. (No model.)

Claim.—1. In combination in an incandescent gas-burner, the mantle, a rod for supporting the mantle, means for supporting the rod and a centrally-arranged pivot-support having a pivot-point upon which said supporting means rest, substantially as described.

2. In combination in incandescent lamps, a cone-shaped mixing-chamber having its apex upward, a pivot-support within said cone-shaped mixing-chamber and having its pivot-point located at the apex.

3. In an incandescent burner, the mantle, means for directly supporting the mantle, and a pivot-support therefor including a centrally-arranged pivot-point, substantially as described.

4. In an incandescent burner, the mantle, means for directly supporting the mantle and a pivot-support therefor including a centrally-arranged pivot-point with means for holding the same yieldingly, substantially as described.

5. In combination in an incandescent gas-burner, a mantle, a mixing-chamber and a gallery with means for supporting all the said parts

pivotal, said means including a centrally-arranged pivot-point, substantially as described.

6. In combination in an incandescent gas-burner, a mantle, means for supporting the same directly and a pivot-support comprising a rod extending up into the burner, substantially as described.

7. In combination in an incandescent gas-burner, a mantle, means for supporting the same directly and a pivot-support comprising a rod extending up into the burner, said rod being yieldingly supported, substantially as described.

8. In combination, a mantle, a double-coned mixing-chamber, a rod extending up into the mixing-chamber to support the same pivotally, the said mantle being supported by the said mixing-chamber, substantially as described.

698,483. CAR-COUPLING. DAVID L. BOK, Lebanon, Pa. Filed Feb. 12, 1902. Serial No. 94,266. (No model.)

Claim.—1. A car-coupling having a head provided with a side approximately parallel with the line of draft, a pocket in said side having slanting-shoulders in the sides of the pocket, and a laterally-acting hook having a transverse shoulder, in combination with a laterally-acting latch lying within and pivoted in said pocket with its front end normally engaging the shoulder on the hook, and having lateral extensions engaging said slanting-shoulders.

2. A car-coupling having a pocket in the side of the head provided with slanting-shoulders in the sides and at the rear end of the pocket, and a laterally-acting hook having a transverse shoulder; in combination with a laterally-acting latch having lateral and rearward extensions, lying within and pivoted in said pocket with its front end normally engaging the shoulders on the hook, its lateral extensions engaging the slanting-shoulders in the sides of the pocket, and its rear end engaging the rear wall of said pocket, and an inclined spring engaging the latch.

698,484. CASTING-MACHINE. HENRY L. BOK, Hartford, Conn., assignor to the Vender Manufacturing Company, Hartford, Conn., a Corporation of Connecticut. Filed Apr. 28, 1900. Serial No. 12,577. (No model.)

Claim.—1. In a casting-machine, the combination with a mixing-tank, of a valve-chamber having an inlet-opening from the tank and terminating in a vertically-disposed outlet-opening at its extreme lowest

point, whereby the head of molten metal rendered effective to augment the velocity with which the metal issues downward from said chamber is equated to the total height of the chamber; a well located at one side of the valve-chamber and communicating therewith below the plane of the inlet-opening from the tank; a plunger in the well; and mechanism for controlling the inlet and outlet openings of the valve-chamber.

2. In a casting-machine, the combination with a melting-tank, of a valve-chamber whose side walls converge upwardly on all sides toward a centrally-disposed inlet-opening at its highest point communicating through an upwardly-extending passage-way with the lower portion of the tank, whereby gases and vapors escaping from the molten metal in the chamber may find free vent to the atmosphere; said valve-chamber also terminating in a vertically-disposed outlet-opening at its extreme lowest point, whereby the head of molten metal rendered effective to augment the velocity with which the metal issues downward from said chamber is equated to the total height of the chamber; a well located at one side of the valve-chamber and communicating therewith below the plane of the inlet-opening from the tank; a plunger in the well; and mechanism for controlling the inlet and outlet openings of the valve-chamber.

3. In a casting-machine, the combination with a melting-tank, of a valve-chamber whose side walls converge upwardly on all sides toward a centrally-disposed inlet-opening at its highest point communicating through an upwardly-extending passage-way with the lower portion of the tank, whereby gases and vapors escaping from the molten metal in the chamber may find free vent to the atmosphere; said valve-chamber also terminating in a vertically-disposed outlet-opening at its extreme lowest point, whereby the head of molten metal rendered effective to augment the velocity with which the metal issues downward from said chamber is equated to the total height of the chamber; a well located at one side of the valve-chamber and communicating therewith below the plane of the inlet-opening from the tank; a plunger in the well; and mechanism for controlling the inlet and outlet openings of the valve-chamber.

4. In a casting-machine, the combination with a melting-tank, of a vertically-disposed valve-chamber having a centrally-located inlet-opening at its highest point communicating through an upwardly-extending passage-way with the tank, whereby gases and vapors escaping from the molten metal may find free vent to the atmosphere, said valve-chamber also terminating in a vertically-disposed outlet-opening at its extreme lowest point toward which the side walls of the chamber converge, whereby the vertical downward flow of metal from the chamber is facilitated and the head of molten metal rendered effective to augment the velocity with which the metal issues downward from said chamber is equated to the total height of the chamber; and means for effecting the ejection of molten metal in the valve-chamber through the outlet thereof under a pressure additional to that of its own weight.

5. In a casting-machine, the combination with a melting-tank, of a valve-chamber having an inlet-opening from the tank and terminating in a vertically-disposed outlet-opening at its extreme lowest point, whereby the head of molten metal rendered effective to augment the velocity with which the metal issues downward from said chamber is equated to the total height of the chamber; a well located at one side of the valve-chamber and communicating therewith below the plane of the inlet-opening from the tank; a plunger in the well; and a vertically-disposed valve device in said chamber.

6. In a casting-machine, the combination with a melting-tank, of a valve-chamber having an inlet-opening from the tank and terminating in a vertically-disposed outlet-opening at its extreme lowest point, whereby the head of molten metal rendered effective to augment the velocity with which the metal issues downward from said chamber is equated to the total height of the chamber; a well located at one side of the valve-chamber and communicating therewith below the plane of the inlet-opening from the tank; a plunger in the well; and valves connected to move in unison with each other for controlling the inlet and outlet openings of the chamber.

7. In a casting-machine, the combination with a melting-tank, of a valve-chamber having a centrally-disposed inlet-opening at its highest point communicating through an upwardly-extending passage-way with the tank and also terminating in an outlet-opening at its extreme lowest point having a substantially vertical axis; a well located at one side of the valve-chamber and communicating through a passage-way therewith; a plunger in the well; and mechanism for depressing said plunger below the plane of the upper surface of the passage-way by which it communicates with the valve-chamber and for controlling the inlet and outlet openings of said chamber.

8. In a casting-machine, the combination with a vacuum-chamber, of a mold located therein; a melting-tank on top of the vacuum-chamber; a valve-chamber whose side walls converge upwardly on all sides toward a centrally-disposed inlet-opening which communicates through an upwardly-extending passage-way with the lower portion of the tank, whereby gases and vapors escaping from the molten metal in the chamber may find free vent to the atmosphere; valves for controlling the inflow of molten metal to the chamber and its outflow therefrom; a well located at one side of the valve-chamber and communicating therewith below the plane of the inlet-opening from the tank; a plunger in the well; a power-

driven device in the machine; and mechanism operatively connected with each device for actuating the valves and the plunger in proper sequence.

9. In a casting-machine, the combination with a vacuum-chamber, of a mold located therein; a melting-tank on top of the vacuum-chamber; a valve-chamber terminating in a vertically-disposed outlet-opening at its extreme lowest point, whereby the head of molten metal rendered effective to augment the velocity with which the metal issues downward from said chamber is equated to the total height of the chamber; a well located at one side of the valve-chamber and communicating therewith below the plane of the inlet-opening from the tank; a plunger in the well; a power-driven device in the machine; and mechanism operatively connected with each device for actuating the valves and the plunger in proper sequence.

10. In a casting-machine, the combination with a mold, of a vacuum-chamber located therein; a melting-tank on top of the vacuum-chamber; a valve-chamber whose side walls converge upwardly on all sides toward a centrally-disposed inlet-opening communicating through an upwardly-extending passage-way with the lower portion of the tank, whereby gases and vapors escaping from the molten metal in the chamber may find free vent to the atmosphere; said valve-chamber also terminating in a vertically-disposed outlet-opening at its extreme lowest point, whereby the head of molten metal rendered effective to augment the velocity with which the metal issues downward from said chamber is equated to the total height of the chamber; a well located at one side of the valve-chamber and communicating therewith below the plane of the inlet-opening from the tank; a plunger in the well; valves for controlling the inlet and outlet openings of the valve-chamber; a power-driven device in the machine; and mechanism operatively connected with each device for actuating the valves and the plunger in proper sequence.

11. In a casting-machine, the combination with a separable mold, of a vacuum-chamber located therein; a melting-tank on top of the vacuum-chamber; a valve-chamber whose side walls converge upwardly on all sides toward a centrally-disposed inlet-opening communicating through an upwardly-extending passage-way with the lower portion of the tank, whereby gases and vapors escaping from the molten metal in the chamber may find free vent to the atmosphere, said valve-chamber also terminating in a vertically-disposed outlet-opening at its extreme lowest point whereby the head of molten metal rendered effective to augment the velocity with which the metal issues downward from said chamber is equated to the total height of the chamber; a well located at one side of the valve-chamber and communicating therewith below the plane of the inlet-opening from the tank; a plunger in the well; valves for controlling the inlet and outlet openings of the valve-chamber; a power-driven device in the machine; and mechanism operatively connected with each device for actuating the valves and the plunger in proper sequence.

12. In a casting-machine, the combination with a vacuum-chamber, of a separable mold located therein; a melting-tank on top of the vacuum-chamber; a valve-chamber having an inlet-opening at its highest point communicating through an upwardly-extending passage-way with the lower portion of the tank, and also terminating in an outlet-opening at its lowest point; valves for controlling the inlet and outlet openings; a well located at one side of the valve-chamber and communicating therewith; a plunger in the well; a spring for closing the outlet-valve; and means for opening the same.

13. In a casting-machine, the combination with a mold, of a melting-tank; a well communicating with the tank; a plunger in the well for injecting molten metal into the mold; and means for tipping and thereby emptying the tank.

14. In a casting-machine, the combination with a frame, of a removable auxiliary frame supported on the main frame; a mold; a melting-tank supported by the auxiliary frame; a valve-chamber communicating with the interior of the melting-tank and provided with an outlet-opening at its lowest point; a plunger at the side of the valve-chamber for injecting molten metal into the mold; and means for tipping and thereby emptying the tank.

15. In a casting-machine, the combination with a separable vacuum-chamber, of a mold located therein; a bell for removing the movable member of the chamber; mold-filling means supported on the movable member; a melting-tank also located on said movable member; and means for tipping said movable member to empty the tank carried thereon.

16. In a casting-machine, the combination with a main frame, of a mold carried thereby; mold-filling means removable from the main frame and operative for forcing molten metal under high pressure into the mold; a bell pivoted to the mold-filling means; and mechanism for tipping the mold-filling means relatively to said bell.

17. In a casting-machine, the combination with a main frame, of a mold carried thereby; mold-filling means removable from the main frame and operative for forcing molten metal under high pressure into the mold; a bell pivoted to the mold-filling means; and gearing mechanism for tipping the mold-filling means relatively to said bell.

18. In a casting-machine, the combination with a main frame, of a mold carried thereby; mold-filling means removable from the main frame and operative for forcing molten metal under high pressure into the mold; a bell pivoted to the mold-filling means; a gear-arrangement movable in unison with the mold-filling means; a rotatable gear carried by said bell and in mesh with said gear-arrangement; and means for turning and for locking said gear.

19. In a casting-machine, the combination with a vacuum-chamber, a mold located therein; a melting-tank adapted to be filled from its normal position; means for injecting metal into the mold; and means for tipping and thereby emptying the tank.

20. The combination with a separable vacuum-chamber, of a mold located therein; means for clamping the sections of the vacuum-chamber together; a melting-tank; means for injecting metal into the mold located on the movable section of the vacuum-chamber; and means for tipping and thereby emptying the tank.

21. In a casting-machine, the combination with a mold, of a bell; a vacuum-chamber having a removable cover pivoted to said bell; mold-filling means mounted on said cover; and means for tipping said mold-filling means.

22. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of mold-filling means; movable and stationary deflectors for directing molten metal and drip material into different paths, one or least of the drip-deflectors being mounted independently of the mold; and means for actuating said independently-mounted deflector.

23. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of mold-filling means; means for shifting the mold and mold-filling means with relation to each other; a combined drip-receiver and drip-deflector mounted independently of the mold; and means for shifting said drip-deflector between the mold and the mold-filling means upon the withdrawal of the mold from the mold-filling means.

24. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of mold-filling means; means for shifting the mold and mold-filling means with relation to each other, a drip-deflector, and a combined drip-receiver and drip-deflector movable between the mold and the mold-filling means.

25. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of mold-filling means; means for shifting the mold and mold-filling means with relation to each other, and an inverted-V-shaped combined drip-receiver and drip-deflector movable between the mold and the mold-filling means.

26. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of mold-filling means; means for shifting the mold and mold-filling means with relation to each other; a drip-deflector movable between the mold and the mold-filling means; and a removable drip-receiver attached to and removable from the vacuum-chamber.

27. In a casting-machine, the combination with a mold and with mold-filling means, of means for shifting one of said elements toward and from the other; a drip-deflector movable between the mold and the mold-filling means; a second drip-deflector below said first drip-deflector; and a drip-receiver below said second drip-deflector.

28. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of mold-filling means; means operatively connected to the machine for shifting the mold and mold-filling means with relation to each other; a drip-deflector mounted independently of the mold; means for shifting said deflector between the mold and the mold-filling means upon the separation of the two; and a casting-receiver located below the mold.

29. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of mold-filling means; means operatively connected to the machine for shifting the mold and mold-filling means with relation to each other; a drip-deflector mounted independently of the mold and having a deflecting-flap inclined in one direction; means for shifting said deflector between the mold and the mold-filling means upon the separation of the two; and a casting-deflector located below the mold and having a deflecting-flap inclined in a different direction.

30. In a casting-machine, the combination with a vacuum-chamber and a separable mold located therein embodying a plurality of mold-sections, of mold-filling means; means operatively connected with the machine for shifting the mold and mold-filling means with relation to each other; mold-operating means for parting the mold-sections; a drip-deflector mounted independently of the mold; means for shifting the deflector between the mold and mold-filling means upon the separation of the two; and a casting-deflector disposed substantially below the mold-filling means.

31. In a casting-machine, the combination with a vacuum-chamber and with a mold located therein, of mold-filling means; means for shifting the mold and mold-filling means with relation to each other; a drip-receiver located at one side of the mold; a casting-receiver located at the other side of the mold; drip-deflecting means mounted independently of

the mold; means for shifting the drip-deflecting means between the mold and the mold-filling means upon the separation of the two; and casting-deflecting means located above the casting-receiver.

32. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of mold-filling means; means operative from the machine for shifting the mold and mold-filling means with relation to each other; a drip-receiver located at one side of the mold; a casting-receiver located at the other side of the mold; drip-deflecting means movable between the mold and the mold-filling means and located above the drip-receiver; a mold-carrier; and casting-deflecting means supported on the mold-carrier.

33. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of superposed mold-filling means having a discharge-nozzle; means operatively connected to the machine for raising and lowering the mold; a reciprocating drip-deflector mounted independently of the mold; and means for shifting the drip-deflector into a position under the discharge-nozzle.

34. In a casting-machine, the combination with a mold and with superposed mold-filling means having a discharge-nozzle, of a mold-carrier movable toward and from said discharge-nozzle; a drip-receiver movable into position under said discharge-nozzle; and casting-deflecting means supported on the mold-carrier and movable therewith.

35. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of superposed mold-filling means having a discharge-nozzle; means operatively connected to the machine for raising and lowering the mold into and out of contact with the nozzle; a drip-deflector mounted independently of the mold; and power-operated means for shifting the drip-deflector into position under the discharge-nozzle on the lowering of the mold, and for withdrawing the same from between the mold and the nozzle to permit the mold to be raised.

36. In a casting-machine, the combination with a vacuum-chamber having an opening therein, of a mold within said chamber; superposed mold-filling means having a discharge-nozzle; means for raising and lowering the mold; an operating member working in said opening; an abutment packing between the operating member and the walls of said opening; and a drip-receiver controlled by said operating member and movable into position under said discharge-nozzle on the lowering of the mold.

37. In a casting-machine, the combination with a mold and with superposed mold-filling means having a discharge-nozzle, of means for raising and lowering the mold, and a drip-receiver below said discharge-nozzle and having an opening through which the upper portion of the mold is movable.

38. In a casting-machine, the combination with a mold and with superposed mold-filling means having a discharge-nozzle, of means for raising and lowering the mold; a drip-receiver below said discharge-nozzle and having an opening through which the upper portion of the mold is movable; and a drip-deflector movable in said drip-receiver into position under said discharge-nozzle.

39. In a casting-machine, the combination with a mold and with superposed mold-filling means having a discharge-nozzle, of means for raising and lowering the mold; a drip-receiver below said discharge-nozzle and having an opening through which the upper portion of the mold is movable; and an inverted-V-shaped drip-deflector movable in said drip-receiver into position under said discharge-nozzle and having its flaps inclined toward the sides of said drip-receiver.

40. In a casting-machine, the combination with a mold and with superposed mold-filling means having a discharge-nozzle, of means for raising and lowering the mold; a drip-deflector movable into position under said discharge-nozzle; a second drip-deflector located below the first drip-deflector and having an opening through which the upper portion of the mold is movable; and a drip-receiver located below the second drip-deflector.

41. In a casting-machine, the combination with a vacuum-chamber having an opening therein, of a separable mold located within said chamber and having a pair of mold-sections; mold-filling means; mold-operating mechanism; an operating member working in said opening; an air-tight packing between the operating member and the walls of said opening; and a mold-cleaning brush controlled by said operating member and movable between the opened mold-sections.

42. In a casting-machine, the combination with a vacuum-chamber, of mechanism including a mold located therein; mold-filling means; a driving member; a valve controlled in its movements by said driving member; a meter having a piston operatively connected with a member of the mechanism within said vacuum-chamber; and means controlled by said valve for supplying the meter with a motive fluid.

43. In a casting-machine, the combination with a vacuum-chamber, of mechanism including a mold located therein; mold-filling means; a driving member located outside the vacuum-chamber; a piston-valve controlled in its movements by said driving member; a meter having a piston operatively connected with a member of the mechanism within said vacuum-chamber; and means controlled by said valve for supplying the meter with a motive fluid.

vacuum-chamber; and means controlled by said valve for supplying the motor with a motive fluid.

44. In a casting-machine, the combination with a vacuum-chamber, of mechanism including a mold located therein; a driving member located outside the vacuum-chamber; a piston-valve controlled in its movements by said driving member; a motor also located outside the vacuum-chamber and having a piston operatively connected with a member of the mechanism within the vacuum-chamber, said member working through an opening therein; means controlled by said valve for supplying the motor with a motive fluid; and an air-tight packing between said member and the wall of said opening.

45. In a casting-machine, the combination, with a vacuum-chamber having an opening therein, of a mold within said chamber; superposed mold-filling means having a discharge-nozzle; means for raising and lowering the mold; a driving member located outside the vacuum-chamber; a fluid-controlling piston-valve controlled in its movements by said driving member; a fluid-motor also located outside the vacuum-chamber and having a piston; fluid-supplying means connected and communicating with the motor and with the piston-valve; a piston-rod working in said opening in the chamber; an air-tight packing between the piston-rod and the walls of said opening; and a drip-receiver located wholly within said chamber and movable into position under said discharge-nozzle and controlled by said piston-rod.

46. In a casting-machine, the combination, with a vacuum-chamber having an opening therein, of a mold within said chamber; superposed mold-filling means having a discharge-nozzle; means for raising and lowering the mold; a driving member located outside the vacuum-chamber; a fluid-controlling piston-valve controlled in its movements by said driving member; a fluid-motor also located outside the vacuum-chamber and having a piston, and also having a piston-rod working in said opening in the chamber; fluid-supplying means connected and communicating with the motor and with the piston-valve; an air-tight packing between the piston-rod and the walls of said opening; and a drip-receiver located wholly within said chamber and movable into position under said discharge-nozzle and connected with said piston-rod.

47. In a casting-machine, the combination with a vacuum-chamber and a mold located therein, of mold scraping and cleaning mechanism; mold-filling means; driving means; a pair of differentially-operative valves controlled in their movements by the driving means; a pair of fluid-motors having pistons; fluid-supplying means connected and communicating with each motor and with the valve corresponding to each motor; and means connecting the said pistons with the mold scraping and cleaning mechanism for effecting the operation thereof.

48. In a casting-machine, the combination, with a mold embodying a pair of mold-sections, of mold-filling means; mold-separating means for shifting said mold-sections in different directions; and a pair of mold-scrapers mounted respectively on said mold-sections and movable relatively thereto across the cheeks thereof.

49. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and shiftable vacuum-maintaining casting-receiver means for sealing said opening.

50. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and vacuum-maintaining means embodying a casting-receiver and a valve reciprocally effective for sealing said opening.

51. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and vacuum-maintaining means embodying a casting-receiver and a valve movable in unison and reciprocally effective for sealing said opening.

52. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and vacuum-maintaining means embodying a casting-receiver and a shiftable valve reciprocally effective for sealing said opening.

53. In a machine of the class specified, the combination with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and vacuum-maintaining means embodying a shiftable casting-receiver and a valve reciprocally effective for sealing said opening.

54. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and vacuum-maintaining means embodying a casting-receiver and a slide-valve secured thereto and effective reciprocally therewith for sealing said opening.

55. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and a plurality of shiftable vacuum-maintaining casting-receivers separately effective for sealing said opening.

56. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and a pair of shiftable vacuum-maintaining casting-receivers alternately effective for sealing said opening.

57. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and a plurality of shiftable vacuum-maintaining casting-receivers separately effective for sealing said opening.

58. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and a plurality of shiftable vacuum-maintaining casting-receivers movable in unison and separately effective for sealing said opening.

59. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; a pair of shiftable vacuum-maintaining casting-receivers alternately effective for sealing said opening; and means effective reciprocally with said casting-receivers respectively for also sealing said opening.

60. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said opening; mold-filling means; a pair of shiftable vacuum-maintaining casting-receivers alternately effective for sealing said opening; and a cut-off plate connecting said casting-receivers and effective reciprocally with said receivers respectively for also sealing said opening.

61. In a machine of the class specified, the combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; a pair of connected shiftable vacuum-maintaining casting-receivers separately effective for sealing said opening; and a rack-and-pinion movement for shifting said receivers.

62. In a casting-machine, the combination, with a support, of a molting-tank; an operated member mounted in the molting-tank and adapted to govern the flow of molten metal; an operating member disposed in parallelism with said operated member; and a pivoted connector detachably secured to said operating and operated members respectively and detachable therefrom by a movement in the plane of its oscillation.

63. In a casting-machine, the combination, with a support, of a molting-tank mounted thereon and vertically removable therefrom; a vertically-disposed valve mounted in the molting-tank; a valve-operating member disposed in parallelism with said valve; and a horizontally-disposed pivoted connector detachably secured to the valve and the valve-operating member respectively, and detachable therefrom by swinging it in the plane of its oscillation.

64. In a casting-machine, the combination, with a support, of a molting-tank mounted thereon and vertically removable therefrom; a vertically-disposed valve mounted in the molting-tank; a plunger also mounted in the molting-tank and parallel with said valve; valve-operating and plunger-operating members disposed in parallelism with said valve and plunger; and a pair of horizontally-disposed pivoted connectors detachably connected, the one to the valve and the valve-operating member respectively, and the other to the plunger and the plunger-operating member respectively, and detachable by swinging them in their respective planes of oscillation.

698,485. COLLAPSE CRATE. ERNEST D. BROWN, Delaware, Ohio, assignor of one-half to AUGUST F. MILLER, Delaware, Ohio. Filed Aug. 22, 1901. Serial No. 72,901. (No model.)

Claim.—1. In a device of the class specified, the combination of the top, bottom, side and end portions each formed of a separate section, and arranged in pairs, one pair of sections being provided with a plurality of openings, and the remaining sections having transverse adapted to said openings, the transverse of one pair being longer than those of the opposite pair of sections, the longer transverse being adapted to be entered in their respective openings in advance of the shorter transverse.

2. In a device of the class specified, the combination of the end sections having vertical and horizontal edge bars or strips, there being one set of openings in the vertical bars, and a second set of openings extending through both the vertical and horizontal bars, side sections having at

their ends short tenons adapted to the first set of openings, and top and bottom sections having longitudinal bars or strips provided at their opposite ends with elongated tenons adapted to the second set of openings.

2. In a device of the class specified, a trap or lid adapted to cover an opening in the top of the crate, said trap or lid having an endwise movement to effect its engagement with or disengagement from a slot or keeper in the crate, a spring connected centrally to said trap or lid, the opposite ends of said spring being adapted to guides carried by the crate, said spring acting as a fulcrum for the lid and also tending to retain the same in locked position.

698,486. MALLET. WALTER R. DUNN, Boston, Mass. Filed Dec. 19, 1891. Serial No. 88,482. (No model.)

Claim.—1. In combination, a mallet-head; a handle-shank formed with a flanged part substantially integral therewith and non-rotatable thereon, and secured to said mallet-head by means locking by rotation; said securing means locking by rotation; a locking-dovetail formed with an aperture adapted to receive said flanged part and to prevent said flange from turning therein; and interlocking means between said mallet-head and said locking-dovetail which prevent said locking-dovetail from rotating.

2. In combination, a mallet-head; a handle-shank provided with a flanged part polygonal in outline, substantially integral therewith and non-rotatable thereon, and secured to said mallet-head by means locking by rotation; said securing means which lock by rotation; a locking-dovetail formed with an aperture adapted to receive said flanged part; and a lag-and-socket connection between said mallet-head and said locking-dovetail, to prevent said locking-dovetail from rotating.

3. In combination, a mallet-head made up of separable parts; a securing device for holding the parts of said mallet-head together; a locking-dovetail which engages said securing device and prevents it from turning therein; interlocking means between said mallet-head and said locking-dovetail to prevent said locking-dovetail from rotating; a handle-shank engaged non-rotatably with said locking-dovetail, and secured to said mallet-head by means which lock by rotation; and said securing means which lock by rotation.

4. In combination, a mallet-head made up of separable parts; a nut for holding the parts of said mallet-head together; a nut-lock which engages said nut and prevents it from turning therein; a lag-and-socket connection between said mallet-head and said nut-lock to prevent said nut-lock from rotating; a handle-shank engaged non-rotatably with said nut-lock and secured to said mallet-head by means which lock by rotation; and said securing means which lock by rotation.

5. A mallet-head made up of small, between which is interposed a body portion of wood or other suitable material, said small and body portion being suitably connected to form a separable member; said body portion; a disk provided with a stem; an annular disk secured on said stem; said small and said disk being connected by a lag-and-socket connection.

6. In combination, a pair of small suitably secured together; a body portion of wood or other suitable material interposed between said small; a disk secured to one of said small by a lag-and-socket connection to prevent turning of said small; a handle; and means for connecting said disk to said handle.

7. A mallet made up of the following instrumentalities, viz: a mallet-head; a handle-shank secured thereto by means which lock by rotation and engaged non-rotatably with a nut-lock; said securing means which lock by rotation; and said nut-lock engaged non-rotatably with said mallet-head.

8. A mallet made up of the following instrumentalities, viz: a mallet-head; a handle-shank yieldingly secured thereto by means which lock by rotation and engaged non-rotatably with a nut-lock; said securing means which lock by rotation; and said nut-lock engaged non-rotatably with said mallet-head.

698,487. MAGNETIC FEELER FOR LOOM. CHARLES P. NEUMAN, New York, N. Y., assignor of one-half to Coleman E. Seber, Louisville, Pa. Filed Aug. 9, 1891. Serial No. 71,501. (No model.)

Claim.—1. In a loom, the combination with a shuttle having a magnetizable filling-carrier, of a permanent magnet and a feeler consisting of a magnetizable rod movable in contact with said magnet and extending into the path of the filling-carrier.

2. In a loom, the combination with a shuttle having a magnetizable filling-carrier, of a hollow permanent magnet and a feeler consisting of a magnetizable rod movable within the magnet and extending into the path of the filling-carrier.

3. In a loom, the combination with a shuttle having a magnetizable filling-carrier, of a hollow permanent magnet having an elongated head projecting beyond the breast-beam of the loom, and a feeler consisting of a magnetizable rod movable within the magnet and extending into the path of the filling-carrier.

4. In a loom, the combination with a shuttle having a magnetizable filling-carrier, of a hollow permanent magnet having an elongated tapering head projecting beyond the breast-beam of the loom, and a feeler consisting of a magnetizable rod movable within the magnet and extending into the path of the filling-carrier.

5. In a loom, the combination with a shuttle having a magnetizable filling-carrier, of a hollow permanent magnet having an elongated head projecting beyond the breast-beam of the loom, and a feeler consisting of a magnetizable rod movable longitudinally within the magnet and extending into the path of the filling-carrier, the outer end of said head being in contact with and forming a guide for the feeler.

6. In a loom, the combination with a shuttle having a magnetizable filling-carrier, of a hollow permanent magnet having an elongated head projecting beyond the breast-beam of the loom, said head having a longitudinal tapering bore, of a feeler consisting of a magnetizable rod movable longitudinally through the magnet and in contact therewith only at the outer end of said tapering bore.

7. In a loom, the combination with a shuttle having a magnetizable filling-carrier, of a hollow permanent magnet, a feeler consisting of a magnetizable rod extending through and movable longitudinally within the magnet, said rod being in contact with the magnet at its forward end only, and a magnetizable spring arranged in the path of the rear end of said rod.

8. In a loom, the combination with a shuttle having a magnetizable filling-carrier, of a hollow permanent magnet, a feeler consisting of a magnetizable rod extending through and movable longitudinally within the magnet, said rod being in contact with the magnet at its forward end only and having a head at its rear end and a magnetizable spring in the path of said latter head.

9. In a loom, the combination with a shuttle having a magnetizable filling-carrier, of a hollow permanent magnet comprising an annularly-arranged group of magnetized wires, a non-magnetic casing surrounding said wires, a magnetizable head in contact with the wires at one end of the casing, said head having an elongated tubular extension, a non-magnetic head at the opposite end of the casing and a feeler consisting of a magnetizable rod extending through said head.

10. In a loom, the combination with a shuttle having a magnetizable filling-carrier, of a magnetizable feeler, the forward end of which is arranged in the path of said carrier, a magnet arranged to magnetize said

feeler stronger at the forward end than at the rear end, and a magnetic spring arranged in the path of said rear end.

698,488. DOUBLING APPARATUS. CHARLES W. BRAY, Pittsburgh, Pa., assignor to American Tin Plate Company, Orange, N. J., a Corporation of New Jersey. Filed Jan. 2, 1900. Serial No. 98,571. (No model.)

Claim.—1. In doubling apparatus, a pair of grooved rollers, a pusher blade having projecting fingers rigidly secured thereto and arranged to enter the grooves, and mechanism for reciprocating the blade; substantially as described.

2. In doubling apparatus, a pair of grooved rolls, a pair of plain-faced rolls arranged in tandem therewith, a pusher blade having projecting fingers rigidly secured thereto and arranged to enter the recessed portions of the grooved roll, and mechanism for reciprocating the pusher blade; substantially as described.

698,489. SHIFTING MECHANISM FOR STEERING OR OTHER PURPOSES. GEORGE C. BAKER, When, N. Y. Filed Aug. 2, 1891. Serial No. 71,374. (No model.)

Claim.—1. A shifting mechanism of the class described, comprising a rotatable and longitudinally-movable interiorly-threaded sleeve, and a longitudinally-movable shift-rod exteriorly threaded to engage with the interior threads of the sleeve.

2. A shifting mechanism of the class described, comprising a suitable support having threaded bearings, an interiorly-threaded rotatable sleeve, interior threads engaging said threaded bearings, and a longitudinally-movable shift-rod having its threads engaging the interior threads of the sleeve and reversely related to the exterior threads of the latter.

3. A steering mechanism of the class described, comprising a support having threaded bearings, an exteriorly and interiorly threaded sleeve working in said bearings and formed in sections, a differential coupling connecting the sections of said sleeve, and an exteriorly-threaded shift-rod having its threads engaging the interior threads of the sleeve and reversely related to the exterior threads of the latter.

4. A shifting mechanism of the class described, comprising a support having threaded bearings, an exteriorly and interiorly threaded sleeve engaging said bearings and having separate sections provided with adjacent differently-threaded ends, and a coupling-sleeve engaging said differently-threaded ends and combining therewith to form a differential coupling, and a threaded shift-rod engaging the interior threads of the sleeve.

5. A shifting mechanism of the class described, comprising a support having threaded bearings, an exteriorly and interiorly threaded sleeve engaging said bearings, a shift-rod having a threaded portion engaging the interior threads of the sleeve, and an operating device including a rotatable gear having a feathered connection with said sleeve.

698,440. GUN-LOCK. DANIEL BROWN, Cranston, R. I. Filed Feb. 12, 1898. Serial No. 98,734. (No model.)

Claim.—1. In a gun-lock, the combination of a pivotally-mounted hammer, a hammer-spring, a pivotally-mounted main trigger engageable with said hammer, a set trigger centrally mounted in said main trigger at a point to the rear of the pivotal mounting of said main trigger and having a curved upper end, a spring adapted to bear downward on the main trigger, a spring provided with means adapted to bear upward against the upper curved end of said set trigger and so to tend to counteract the effect of the main-trigger spring, and means to secure said springs in position, substantially as specified.

2. In a gun-lock, the combination of a pivotally-mounted hammer, a hammer-spring, a pivotally-mounted main trigger engageable with said hammer, a set trigger centrally mounted in said main trigger at a point to the rear of the pivotal mounting of said main trigger and having a bent upper end, a spring having a central aperture and also a hole near one end, which spring is adapted to exert a downward pressure upon the main trigger, a spring having a longitudinal slot near one end and provided with means at its opposite end adapted to exert an upward pressure upon the upper bent end of the set trigger, means of securing all said springs in position, a screw passing through the slot of the set-trigger spring and through the said hole in the main-trigger spring into the case or frame of the gun-lock, and a set-screw passing through said case or frame, and loosely through said aperture of the main-trigger spring and bearing against the set-trigger spring, substantially as shown.

3. In a gun-lock, the combination of a pivotally-mounted hammer, a hammer-spring, a pivotally-mounted main trigger engageable with said hammer, a set trigger centrally mounted on the main trigger eccentrically thereto and provided with an upper bent end, a spring adapted to exert a downward pressure on the main trigger, a spring adapted to exert an upward pressure on the upper bent end of the set trigger, means for adjusting said set-trigger spring longitudinally, and means for securing all said springs in position, substantially as set forth.

4. In a gun-lock, the combination of a pivotally-mounted hammer, a hammer-spring, a pivotally-mounted main trigger engageable with said hammer, a set trigger centrally mounted on the main trigger eccentrically thereto and provided with an upper bent end, a spring adapted to exert a downward pressure on the main trigger, a spring adapted to exert an upward pressure on the upper bent end of the set trigger, means adapted to regulate the tension of said set-trigger spring, and means for securing all said springs in position substantially as described.

5. In a gun-lock, the combination of a pivotally-mounted hammer, a hammer-spring, a pivotally-mounted main trigger engageable with the hammer, a set trigger mounted in the main trigger eccentrically thereto, a spring adapted to exert a downward pressure upon the main trigger and a spring adapted to exert an upward pressure upon the set trigger, substantially as shown.

6. In a gun-lock, the combination of a pivotally-mounted hammer, a hammer-spring, a pivotally-mounted main trigger engageable with said hammer, a set trigger mounted upon the main trigger eccentrically thereto and two springs adapted to exert their pressure in directions opposite to each other, one of which springs is adapted to operate on the main trigger and the other of which springs is adapted to operate on the set trigger, substantially as specified.

7. In a gun-lock, the combination of a pivotally-mounted hammer, a hammer-spring, a pivotally-mounted main trigger engageable with said hammer, a set trigger mounted upon the main trigger eccentrically thereto, a spring adapted to operate said main trigger provided with a hole near one end and with a series of parallel transverse corrugations of said end, a spring adapted to operate said set trigger having one end curved or bent transversely so as to be engageable with either of the corrugations of the main-trigger spring and provided with a longitudinal slot near said end, and a screw passing through the slot of the set-trigger spring and through the hole in said main-trigger spring into the frame or case of the gun-lock, substantially as described.

8. In a gun-lock, the combination of a pivotally-mounted hammer, a hammer-spring, a pivotally-mounted main trigger engageable with said hammer, a set trigger mounted upon the main trigger concentrically thereto, a spring adapted to operate said main trigger and provided with two holes and with a series of parallel transverse serrations at one end, a spring adapted to operate said set trigger having a longitudinal slot near one end and said end curved or bent transversely so as to be engageable with either of said serrations of the main-trigger spring, a screw passing through the slot of said set-trigger spring and through one of the holes in the main-trigger spring into the case or frame of the gun-lock, and a set-screw passing through said case or frame and loosely through the other hole in the main-trigger spring and bearing against the under side of the set-trigger spring, substantially as specified.

9. In a gun-lock, the combination of a pivotally-mounted hammer having a firing-notch and a safety-notch, a hammer-spring, a pivotally-mounted main trigger engageable with said hammer in either notch thereof, a set trigger centrally mounted on the main trigger concentrically thereto and provided with an upper bent and constituting an enlarged head adapted to counterbalance the opposite end of said set trigger, a spring adapted to exert a downward pressure on the main trigger, a spring adapted to exert an upward pressure on the upper end of the set trigger, and means for securing all said springs in position, substantially as described.

698,441. GRINDING-MILL. JAMES BROWN, Lorain, Ohio. Filed Feb. 5, 1901. Serial No. 61,047. (No model.)

Claim.—1. A grinding-mill, comprising a casing, grinding-heads arranged in said casing, a shaft on which one of the grinding-heads is rigidly mounted, a shaft having a ball at one end engaging a socket in the other head, a clutch-section secured to the said head and having a portion of the socket for the ball formed therein, a clutch-section secured to the shaft, the said clutch-sections having short intermeshing teeth arranged to permit of one clutch-section having a slight rocking motion with reference to the other clutch-section, and a coiled spring surrounding the clutch-sections and bearing at its ends upon said clutch-sections, substantially as specified.

2. A grinding-mill comprising a casing, two grinding-heads arranged in said casing, a shaft with which one of said heads has a universal connection so that it may swing relatively to its shaft, a clutch member attached to the swinging head, a clutch member attached to the shaft and provided with a flange, the said clutch members having intermeshing teeth arranged to permit of one clutch member swinging on the other, and a spring encircling the clutch members and bearing at one end against the clutch member attached to the head and at the other end against the flange of the other clutch member, substantially as specified.

3. In a grinding-mill, a grinding-head, a clutch member secured to the head, a shaft having a ball at one end engaging a socket in the head and in the said clutch member, a clutch member secured to the shaft and meshing with the clutch member on the head, and a spring encircling the clutch members and bearing at its ends thereon, substantially as specified.

698,442. HOOP-FORMING MACHINE. NORMAN E. BROWN, St. Joseph, Mo. Filed Dec. 12, 1900. Serial No. 60,201. (No model.)

Claim.—1. In a hand-operated hoop-forming machine, a rotatable work-support having a hoop-supporting rim, a clamp forming part of the rim and pivotally mounted on said support near the periphery thereof, said clamp having an inwardly-extending arm provided with a stud, an operating-handle having a bifurcated extension for engaging with said stud, whereby on the initial movement of the handle in one direction the clamp will be caused to engage with the end portion of the hoop and then the same against the work-support, and the continued movement of the handle in the same direction will be imparted through the clamping member and the hoop to effect the rotation of said work-support.

2. In a hoop-forming machine, the combination of a rotatable work-support having a peripherally-corrugated portion, a roller having a movement in a plane at right angles to the plane of rotation of the support, a clamp for retaining the joint of a hoop on said support over said corrugated portion and a reinforce applied under said corrugated portion.

3. In a hoop-forming machine, the combination of a rotatable work-support, a horizontally-disposed slidable bar provided with a retracting-spring and also having a vertical movement, the said bar carrying a roller at its front extremity which extends over the support, and means for operating said bar to elevate it and impel it forwardly over the support.

4. In a hoop-forming machine, the combination of a rotatable work-support, and a vertically-movable pressure-roller over the work-support and slidable in a horizontal plane.

5. In a hoop-forming and stapling machine, the combination of a rotatable work-holder having a rear groove and a shoe normally located in said groove and slidable over a portion of the support for detaching the completed hoop.

6. In a hoop-forming and stapling machine, the combination of a work-support, a horizontally-slidable and vertically-movable device carrying a shoe for detaching the work from the support, and means for operating said device.

7. In a hoop-forming and stapling machine, the combination of a work-support capable of being rotated, a vertically-movable longitudinally-slidable device carrying a pressure-roller and a detaching-shoe at its front extremity for respectively holding down the work and detaching the same when completed, and means for operating said device.

8. In a hoop-forming and stapling machine, the combination of a work-support, a vertically-movable and longitudinally-slidable bar carrying a pressure-roller and a shoe adjacent thereto and having a longitudinal slot therein with a roller extending transversely of the same, and a vertically-screwable operating-rod having an upper end-head with a forwardly and downwardly inclined shoulder engaging said roller.

9. In a hoop-forming machine, the combination of a rotatable work-support having rear grooves, and an upwardly-projecting guard at the rear portion of the support having a front flat face and normally held in immovable position in relation to the support, the said guard having an integral cheek at one end in a plane at right angles thereto and which is adjustable in a part of the machine back of the support, the lower portion of the guard extending into rear grooves of the support.

698,443. NAIL-FASTENER. JOHN H. BROWN, St. Paul, Minn. Filed July 26, 1901. Serial No. 60,700. (No model.)

Claim.—A nail-fastener comprising a frame having hair-pins for securing it on the head, extensible bars slidingly inserted in the frame and provided at their ends with pronged heads adapted to take hold of the inner sides of the hat, and a vertically-slidable rock-shaft journaled in the

frame and having one arm projecting from under the hat, and another arm engaging one of the hat-holding bars, and catches in the frame for said arm to engage, substantially as and for the purpose set forth.

698,444. AUGER. JOHN J. DUNN, San Antonio, Tex. Filed Oct. 26, 1900. Serial No. 34,226. (No model.)

Claim.—1. An auger comprising a frame, a sleeve rotatably mounted in the frame, a hollow cross-sectionally-angular chisel carried by the frame and concentric with the sleeve, said sleeve and chisel receiving an auger-bit to project beyond the chisel, a follower engaged with the sleeve and adapted for engagement with an auger-bit therein, a spindle carried by the follower, means for rotating the follower to operate the auger-bit, and means for feeding the bit through the chisel, substantially as described.

2. A device of the class described, comprising a hollow chisel, a sleeve rotatably connected with the chisel, a bit disposed in the chisel and sleeve and adapted to project through the chisel, a follower in the sleeve for engaging the bit, means for rotating the follower to rotate the bit, and means for adjusting the follower in the sleeve to vary the projection of the bit from the chisel.

3. A device of the class described comprising a frame, a hollow body carried by the frame, a hollow chisel, a sleeve rotatably connected with the frame and chisel, a follower adjustable in the sleeve and adapted to engage a bit disposed within the sleeve and chisel, a spindle carried by the follower, a cross-head in threaded engagement with the spindle, rigid connections between the cross-head and frame, said spindle being adapted for adjustment through the cross-head, to compensate for the adjustment of the follower in the sleeve, and means for rotating the follower to correspondingly move the bit.

4. An auger comprising a frame carrying a hollow chisel, a sleeve rotatably connected with the chisel and frame, a follower in the sleeve and adapted for engagement with an auger-bit therein, a spindle carried by the follower, a cross-head in threaded engagement with the spindle, latches carried by the cross-head, rigid connections pivoted to the frame and adapted for engagement with the latches to hold the cross-head spaced from the frame, said spindle being adapted for adjustment through the cross-head to compensate for the adjustment of the follower in the sleeve to vary the projection of the bit, and means for rotating the follower to correspondingly move the sleeve and bit, substantially as described.

698,445. APPARATUS FOR TURNING OFF COFFEE. VALENTIN G. BERN, CHICAGO, ILL., and GEORGE BART, BOSTON, MASS. Filed Apr. 26, 1902. Serial No. 27,000. (No model.)

Claim.—In a device of the character described, a casing, the upper portions of the ends of said casing having semicircular openings formed therein, the top of said casing being partly open, bars extending the upper end of said casing and secured to the outer face thereof, the ends of said bars projecting beyond the ends of the casing and having segmental recesses formed in the upper ends thereof, a drum located partly in said semicircular openings and the opening in the top, and plates on said drum extending beyond said casing, said plates having a series of segmental apertures formed therein between the inner and outer circumferences of the end plates, said plates secured in said apertures, studs on the said end plates engaging in the said recesses in the bars, one of said studs formed into a crank, guides on the periphery of said drum, and a door operating in said guides, substantially as described.

698,446. RUBBER-TIRE-CUTTING MACHINE. JAMES A. BROWN, Akron, Ohio, assignor to The Goodyear Tire and Rubber Company, Akron, Ohio. Filed July 31, 1901. Serial No. 79,088. (No model.)

Claim.—1. In a rubber-tire-cutting machine having gripping devices for holding the tire for turning and a winding-drum to draw said wire, and means for turning said drum, of a regulating device to equalize the tension of said wire located between said drum and gripping device consisting of a pivoted lever having its opposite arms arranged to maintain the wire, substantially as shown and described.

2. An improved rubber-tire-cutting machine consisting of a metallic plate having opposite end brackets with their faces in the same plane and parallel with the face of said plate, with wire-gripping devices pivotally mounted in said brackets, means for rocking said devices on their pivots, a winding-drum provided with clutch mechanism to grasp said wire and a pivoted lever interposed between said drum and gripping devices having opposite arms to support said wire, and a worm-wheel and worm to turn said drum, substantially as shown and described.

698,447. STRIKER. JONAS I. BELL, Kansas City, Mo. Filed June 1, 1901. Serial No. 30,579. (No model.)

Claim.—1. A syringe-stem having a longitudinal groove at its inner end, a series of outwardly-extensible springs connected at their outer ends with the forward end thereof, a slidable collar on said stem with which the inner ends of said springs are connected and a separate non-rotatable slidable collar hinged to said stem and rigidly connected with the collar supporting said springs and a slidable spring clamping device upon said stem, substantially as described.

2. A syringe-stem and a series of outwardly-extensible springs pivotally connected at their forward ends with the forward end of said stem,

a perforate spring clamping-collar through which the springs extend, and a separate non-rotatable slidable collar, and steps on the inner ends of said springs, and means for retaining said steps in the perforations of said collar.

3. A syringe-stem having a longitudinally-grooved inner end and a series of outwardly-extensible springs pivotally connected at their outer ends with the forward end of said stem, a perforate spring clamping-collar on said stem through which the springs extend, separate non-rotatable, slidable collar on said stem, with which the inner ends of said springs are connected and a key upon one of said collars extending within the groove of said stem.

4. A syringe-stem having an externally-curve-threaded inner end, and a longitudinal groove in said end, a series of outwardly-extensible springs pivotally connected at their outer ends with the forward end of said stem, a perforate spring clamping collar on said stem through which said springs extend, a separate slidable collar with which the inner ends of said springs are connected, and a key preventing the rotation of said collar, extending within said longitudinal groove, a nut on the threaded end of said stem and a screw-joint connecting said nut and collar.

5. A syringe-stem having an externally-curve-threaded inner end and a longitudinal groove in said end, a series of outwardly-extensible springs pivotally connected at their outer ends with the forward end of said stem and steps upon their inner ends, a perforate spring clamping, slidable collar on said stem, through which said springs extend, separate, slidable spring holding and binding collars upon said stem in rear of said clamping-collar, one of which is perforated to receive the inner ends of said springs, and provided with depressions in its rear end to receive the steps on said springs, and a key upon the other collar extending within said longitudinal groove, a screw-joint connecting the said spring holding and binding collars and a nut upon the curve-threaded end of said stem and a screw-joint connecting said nut with the binding-collar.

6. In a syringe, a syringe-manipulator having discharge openings, a series of outwardly-extensible springs connected at their outer ends with the forward end of said nozzle, a collar with which the inner ends of said springs are connected having an helical outer surface and a shoulder, and a concave, perforate plate on said collar.

698,448. MACHINE FOR MANUFACTURING EXPANDED SHEET METAL. WILLIAM L. CALDWELL, New York, N. Y., assignor of one-half to GEORGE BULLOCK, Chicago, Ill. Filed Sept. 21, 1900. Renewed Oct. 2, 1901. Serial No. 78,011. (No model.)

Claim.—1. In a machine for the manufacture of expanded sheet metal, the combination of means for cutting or shearing dies in a sheet, independent means for stretching or expanding the sheet, and independent means for cutting or firing the machine of the expanded sheet, substantially as set forth.

2. In a machine for producing expanded sheet metal, the combination of a suitable shearing device adapted to cut the metal sheet, with a suitable expanding device moving with the sheet and acting to stretch or expand the sheet by power applied to the edges only of the sheet, and means for feeding the sheet from the shearing device to the metal-expanding device, substantially as specified.

3. In a machine for producing expanded sheet metal, the combination of a suitable shearing device adapted to form transversely-staggered strips of longitudinal dies in a sheet of metal, with a suitable expanding device moving with the sheet as it comes from the shearing device and adapted to engage the edges only of the sheet and to stretch or expand the sheet laterally, substantially as and for the purpose set forth.

4. In a machine for producing expanded sheet metal, the combination of suitable means for forming transversely-staggered series of longitudinal dies in a sheet of metal, with suitable expanding means adapted to engage the edges only of the sheet and to gradually expand it laterally throughout its width as the sheet passes through the expanding means, substantially as set forth.

5. In a machine of the character described, the combination of means for feeding a sheet of metal, with means for engaging the sheet at its edges acting to automatically force them apart and then expand the sheet as it is fed along, substantially as set forth.

6. The combination of suitable means for feeding a sheet of

metal, with automatic means adapted to engage the sheet at its edges only and to gradually expand the sheet laterally as it is fed through the machine, substantially as set forth.

7. The combination of suitable means for feeding a sheet of metal, with means located at the side of the path of the sheet and engaging the edges of the sheet and forcing said edges of the sheet in divergent paths as the sheet is fed along, whereby the sheet will be expanded laterally, as set forth.

8. The combination of suitable means for feeding a sheet of metal in the direction of its length, and means located at the side of and automatically engaging the edges of the sheet and forcing them gradually apart at right angles to the direction of feed, as set forth.

9. In a machine for expanding metal, the combination with means for feeding the sheet longitudinally, of expanding devices located at the sides of the sheet and having lateral movements in directions diverging from the direction in which the sheet is fed, substantially as specified.

10. In a machine for expanding metal, device for expanding sheet metal, with means located at the side of the path of the sheet and moving with the sheet while expanding them, and means for feeding the sheet to such expanding device, substantially as specified.

11. In a machine for expanding metal, device for expanding sheet metal consisting of diverging traveling chains provided with means for taking hold of the edges of the sheet, substantially as specified.

12. The combination with rolls for sliding the sheet, with means independent of the sliding-rolls, for expanding the sheet while it is moving from the rolls, said expanding means being located at the side of the sheet, and moving with it in its said movement, substantially as specified.

13. The combination with rolls for sliding the sheet, with means independent of the sliding-rolls for expanding the sheet, said expanding means receiving the sheet from the sliding-rolls and acting on it as it moves, and being located at the side of the sheet, substantially as specified.

14. The combination with the setting-rolls having male and female dies for shaping the openings in the sheet uniformly, of means for feeding the expanded sheet to said rolls with the openings in proper register with the dies, substantially as specified.

698,449. AIR-REMOVER FOR ROLLER-FURNACE. DANIEL CAMPBELL, Portville, Canada. Filed Sep. 21, 1900. Serial No. 30,580. (No model.)

Claim.—1. In a roller-furnace, the combination of an air-pit having the converging walls below the grate, an endless conveyor arranged within the air-pit below the plane of the converging walls thereof, means for supporting and driving said conveyor to propel it in a horizontal path,

on sub-plate supported between the upper and lower ends of the conveyor and close to the upper end thereof, and scraper-bars attached to the conveyor and arranged to sweep close to the sub-plate substantially as and for the purposes described.

2. In a boiler-furnace, the combination of an ash-pit having converging walls which are arranged transversely to the line of the boiler-grate, a metallic sub-plate supported below the converging walls of the ash-pit and having the upstanding flanges, an endless conveyor arranged for its upper end to travel over and close to the sub-plate, and also attached to the conveyor and arranged to sweep close to the sub-plate, substantially as described.

3. In a boiler-furnace, the combination of an ash-pit having converging walls which are arranged transversely to the line of the boiler-grate, a metallic sub-plate supported below the converging walls of the ash-pit and consisting of the flanged sections having detachable interlocking engagement one with the other, and an endless conveyor arranged below said sub-plate and having said sub-plate adapted to sweep close to said sub-plate, substantially as and for the purposes described.

4. A boiler-furnace comprising an ash-pit having the downwardly-converging walls and a conveyor-pit at the intersection of said walls, a horizontally-disposed conveyor mechanism operatively arranged within said conveyor-pit, a grate immediately above the conveyor mechanism, and a dead-plate disposed in the plane of the furnace-grate and hinged to drop downward to an inclined position toward one of the walls of the ash-pit and the conveyor mechanism, the space between said dead-plate and the conveyor-pit being unobstructed and permitting the free passage of cinders and ashes which may be raked from the grate directly to the conveyor mechanism, substantially as and for the purposes described.

5. A boiler-furnace comprising an ash-pit having the downwardly-converging walls meeting in a subjacent conveyor-pit, a cinder-crushing mechanism situated externally to the furnace, a horizontally-traveling ash-conveyor mechanism operatively arranged in the conveyor-pit and having its discharge end terminating at said cinder-crushing mechanism, a grate over the conveyor mechanism, and a cinder collector plate disposed in the same plane as the grate and arranged to drop down below the grate and to be inclined toward one of the walls of the ash-pit and the conveyor mechanism therein, whereby the cinders and ashes will be delivered by the collector-plate to the conveyor and by the latter to the crushing mechanism, substantially as described.

6. A boiler-furnace comprising an ash-pit having the downwardly-converging walls meeting in a subjacent conveyor-pit, a sub-chamber situated at a point outside of the limits of the furnace, a cinder-crushing mechanism in said sub-chamber, a horizontally-movable ash-conveyor within said conveyor-pit and arranged to travel across the furnace and to deliver to the cinder-crushing mechanism, a grate over the conveyor mechanism, a cinder-collector plate mounted in the plane of the boiler-grate and adapted to drop below the grate to assume a lowered position

inclined toward the ash-conveyor, and an elevator mechanism taking its lead from the sub-chamber of said ash-pit, substantially as described.

7. A boiler-furnace comprising an ash-pit having the downwardly-converging walls meeting in a subjacent conveyor-pit, a sub-chamber outside of the furnace, a set of intermeshed cinder-crushing rolls situated within said sub-chamber, means for driving one of the rolls of said set of crushing-rolls, a conveyor-driving shaft geared to one of the rolls of the set, and a horizontally-movable ash-conveyor disposed within the conveyor-pit and engaging with the conveyor-driving shaft, said conveyor being movable in a path transversely across the furnace and said set of rolls and the conveyor being driven in series from a common source of power, substantially as described.

8. A boiler-furnace comprising an ash-pit having the downwardly-converging walls meeting in a subjacent conveyor-pit, an endless conveyor having the parallel chains and the cross-flights arranged to move in a horizontal path through the conveyor-pit and transversely across the furnace, a conveyor-driving shaft engaging with said chains, the individually-supported idler-sprockets engaging with the other end of the conveyor-chains, a sub-chamber disposed outside of the furnace, the yokes and screws for adjusting said idler-sprockets and the chains of the endless conveyor individually, a set of cinder-crushing rollers disposed in the sub-chamber and below the drive-shaft of said endless conveyor which has its delivery end overhanging said crushing mechanism, and gear connections between the conveyor drive-shaft and one roller of the crushing mechanism, substantially as described.

9. A boiler-furnace comprising a grate, an ash-conveyor disposed below the grate, a dead-plate hinged in the horizontal plane of the grate and adjustable to a sloping position below the grate and inclined toward the ash-conveyor, a latch mounted on the dead-plate and arranged to engage with the grate to normally retain said dead-plate in the same plane as the grate, and means for operating the latch mechanism, substantially as described.

10. A boiler-furnace comprising a grate, an ash-conveyor disposed below the grate, a hinged dead-plate adjustable to a sloping position below the grate and inclined toward the ash-conveyor, a latch pivoted to the under side of said dead-plate and arranged to engage the grate and to support the dead-plate in the plane thereof, and a handle or lever connected detachably with said latch, as and for the purposes described.

11. A boiler-furnace comprising a grate, an ash-conveyor disposed beneath the grate, a hinged dead-plate adjustable to a sloping position below the grate and inclined toward the ash-conveyor, a latch pivoted to the under side of the dead-plate, a handle attached to the dead-plate and loosely engaging the latch, and a handle or lever connected detachably to the latch, substantially as described.

12. In a boiler-furnace, the combination with a grate, and a boiler-front having an opening or doorway in the horizontal plane of said grate, a dead-plate hinged to the boiler-front in the horizontal plane of the grate and of said opening, a door hinged in a position to close said opening, a latch on said plate, a handle-bar adapted to be thrust through the opening and adjusted to engage with the latch, and an ash-conveyor below the grate, substantially as described.

13. In a boiler-furnace, the combination of an ash-pit provided with the downwardly-converging walls, a conveyor arranged to join the converging walls of said ash-pit, a boiler-grate, a horizontal return tube or conduit adjacent to said conveyor-pit and substantially in the same plane therewith, an endless conveyor having its active and return leads disposed in a horizontal plane below the ash-pit and arranged to travel in the conveyor-pit and the return-conduit respectively, and blades carried by the conveyor and active in the conveyor-pit only, substantially as described.

14. In a boiler-furnace, the combination of an ash-pit provided with the downwardly-converging walls, a conveyor-pit which joins said converging walls of the ash-pit below the boiler-grate, a horizontal return-conduit adjacent to said conveyor-pit, an endless conveyor having its active and return leads operatively disposed in the conveyor-pit and the conduit respectively and each lead arranged to pursue a horizontal path, gear elements mounted to turn on vertical axes and containing the conveyor, and scraper on said conveyor, substantially as described.

15. In a boiler-furnace, the combination of an ash-pit provided with the downwardly-converging walls, a conveyor-pit joining the converging walls of said ash-pit below the boiler-grate, a return-conduit adjacent to said conveyor-pit, an endless conveyor having the active and return leads thereof movable in a horizontal path through the conveyor-pit and the conduit respectively, and flights which conform to the conveyor-pit and carried by the conveyor to sweep close to the surface of the grate, substantially as described.

698,450. MECHANISM FOR PRODUCING PATTERNS-GRATE. THOMAS GATTEY, Philadelphia, Pa. Filed Sept. 22, 1901. Serial No. 75,305. (No model.)

Claim.—1. In a machine for producing pattern-grate, the combination with punching mechanism, including punches, and devices whereby the punches are operated in pairs, one punch of a pair being rendered active while the other punch is rendered idle, and vice versa, of punch-actuating mechanism, and connections between the same and said devices.

2. In a machine for producing pattern-grate, the combination with punching mechanism, including punches, boys therefor arranged in sets, and means for coupling the boys of the respective sets, of punch-actuating mechanism, and connections between the same and a set of boys.

3. In a machine for producing pattern-grate, the combination with punching mechanism, including punches, boys therefor, operating-rods for said boys, and means for coupling said rods in pairs whereby when one rod of a pair is retracted the other is projected, of punch-actuating mechanism, and connections between the same and one of each pair of said rods.

4. In a machine for producing pattern-grate, the combination with punching mechanism, including punches, boys therefor, operating-rods for said boys, and a flexible coupling for each pair of rods whereby when one rod of a pair is retracted the other is projected, of punch-actuating mechanism, and flexible connections between the same and one of each pair of said rods.

5. In a machine for producing pattern-grate, the combination with punching mechanism, including punches, boys therefor, operating-rods for said boys, said rods being coupled in pairs as described, needles connected with said rods, a reciprocating carriage and means thereon for cutting said needles in normal position, of punch-actuating mechanism including rods, flexible connections between the same and one of each pair of rods first named, needles, connections between the same and the rods of the selecting mechanism, a reciprocating carriage, and an over-head and a cylinder on said carriage adapted to coast with the latter needles.

698,451. IMPROVED BAR CLIP AND NEW. JAMES CHALMERS, Jr., Baltimore, Pa., assignor to The Patent Office and Signal Company, Baltimore, Pa. Filed Oct. 12, 1901. Serial No. 75,175. (No model.)

Claim.—1. A clip for supporting detector-bars, having a body formed of two leaves at an angle to each other, having a supporting-bracket extending from the lower leaf, to which bracket the supporting-arm of the detector-bar is to be pivoted, and having apertures or recesses in both or covers by which the clip is to be secured to the railroad-tie.

2. A clip for supporting detector-bars, consisting of leaves formed at an angle to each other for attachment to the tie, and having a bracket for the radial supporting-arm, extending from one leaf, and a detector-bar stop extending from the other leaf.

3. A clip for supporting detector-bars, consisting of leaves formed at an angle to each other for attachment to the tie, a bracket extending from one leaf, a fixed detector-bar stop extending from the other leaf, and a second stop adjustably secured to the fixed stop.

4. A clip for supporting detector-bars, consisting of two leaves formed at an angle to each other for attachment to the tie, a bracket extending from one leaf and a fixed stop from the other, and a second stop adjustably secured to the fixed stop, and serrations or teeth formed on the meeting faces of the fixed and adjustable stops.

698,452. HOLLOW OR DOUBLE WALLED STRUCTURE. ABOLIO DE CLAMNET, Tupaia, Kama, assignor of one-fourth to T. B. Humphreys, Tupaia, Kama. Filed Aug. 20, 1901. Serial No. 75,116. (No model.)

Claim.—1. A hollow wall having S-shaped grooves or cuts in the lower faces of its sides, and a brace of corresponding S shape having its edge portions fitted in the grooves or cuts of the said sides of the wall, substantially as set forth.

2. In combination with a hollow wall adapted to have the air exhausted from its space, indicating mechanism for determining the degree of exhaustion of the air induced within the space of the said wall and controlled by the lateral movement of the sides of the said wall, substantially as set forth.

3. In combination with a hollow wall adapted to have the air exhausted from the space thereof, studs spaced apart and extended inward from the sides of the said wall, a lever pivotedly connected to the inner ends of said studs, and an indicating mechanism actuated by the said lever to determine the degree of exhaustion of the air in the space of the said wall, substantially as described.

4. In combination with a hollow wall adapted to have the air exhausted from the space thereof, studs extended inwardly from the sides of the said wall, a lever pivotedly connected to the inner ends of said studs, and having a toothed segment at its outer end, a shaft provided with a pinion in mesh with the said toothed segment, a pointer applied to said shaft, and a dial for co-operation with the pointer, substantially as set forth.

698,453. REFRIGERATOR. ABOLIO DE CLAMNET, Tupaia, Kama, assignor of one-fourth to T. B. Humphreys, Tupaia, Kama. Filed Aug. 20, 1901. Serial No. 75,111. (No model.)

Claim.—1. In a structure having hollow walls from which the air is adapted to be exhausted, a valve-controlled communication between said walls for isolating the same after the vacuum has been created, substantially as and for the purposes set forth.

2. A refrigerator or like structure having hollow walls from which air is adapted to be exhausted by application of a pump to a side or wall of the structure, and valve-controlled communication between the space of the several walls to admit of each being isolated after exhaustion of the air, substantially as set forth.

3. In a structure having a hollow wall and a hollow door, a hinge connection between the door and wall, and hinge members having passages in communication with, respectively, the wall and the door, said passages being normally out of register to interrupt communication between the hollow spaces of the wall and door and adapted to be brought into coincident relation by throwing the door open to the limit of its movement, substantially as set forth.

4. A hollow glass panel or window-light having the air exhausted

therefrom and having a transparent brace attached at its ends to opposite walls of said hollow glass panel, substantially as set forth.

698,454. FILLER COMPOUND FOR TIRES. ABOLFO DE CLAIR-BOU, Tepala, Kans., assignor of one-half to Albrecht Harburg, Tepala, Kans. Filed Nov. 7, 1901. Serial No. 31,490. (No specimens.)

Claim.—1. A composition of matter for filling tires consisting of glue, molasses, water and granulated cork in about the proportions specified.
2. A composition of matter for filling tires consisting of glue, molasses, water, resin and granulated cork in about the proportions specified.

698,455. HEATING GAS-BURNER. HOWARD S. CLARK, Boston, Mass. Filed Mar. 21, 1901. Serial No. 34,169. (No model.)

Claim.—1. The combination with a closed burner-chamber having in its top a series of perforations and in its bottom correspondingly-located smaller perforations, of upwardly-removable open tube-sections each having its lower end seated in the bottom in registry internally with one of the perforations therein and with its upper end portion centrally located in the corresponding larger perforation in the top; whereby the upper perforations become annular passages in the zone of which air from below the chamber is delivered by tubes readily removed and inserted through said upper perforations.

2. The combination with a closed burner-chamber having in its top a series of perforations and in its bottom correspondingly-located smaller perforations each surrounded by an annular projection or boss forming a tube-cocket, of upwardly-removable open tube-sections each seated in one of said cockets and having its upper end portion held central in the corresponding larger perforation above and terminating below the upper end of said perforation.

3. In a burner of the class described, the combination with a cup-like lower member divided into non-communicating compartments each having in its bottom perforations surrounded, respectively, by annular projections forming tube cockets or seats, of an upper member closing all the compartments and provided with perforations larger than those below but registering with them and surrounded by analogous bosses, tube-cockets externally of less diameter than the perforations in the top, removably seated in said cockets, respectively, with their upper end portions lying centrally in the perforations of the top, through which they may be readily removed and replaced, mixing-tubes projecting into said compartments, respectively, a vaporizing-tube passing over the perforations in the top of one compartment, injecting-nozzles supplied from said vaporizing-tube and discharging into the outer ends of the mixing-tubes, respectively, means for controlling the supply of the compartment below the vaporizing-tube, and independent means for controlling the supply to the remainder of the burner.

4. The combination with the boiler shell or aliving, of an upper

burner member downwardly closing the shell and provided with a series of perforations each surrounded by an integrally-formed tubular projection or boss, a cup-like lower member separably connected with the upper member, to form therewith a closed chamber, and provided with perforations registering with those above and each surrounded by a tubular projection or boss counterbored to receive a tube from above, and a series of tubes externally of smaller diameter than the perforations in the upper member, removably seated in the counterbored projections, respectively, and each extending centrally into the corresponding perforation in the upper member and upwardly removable therefrom.

698,456. SUSPENDERS AND TROUSERS CONNECTION. RICHARD T. CLARK, Columbus, Ohio. Filed Feb. 28, 1901. Serial No. 34,781. (No model.)

Claim.—In a suspender and trousers connection, the combination with a trousers-band, of a button-engaging device comprising a single piece of spring-steel bent to a substantially M form, the central portion of said body being bent to a substantially heart shape and comprising adjacent loops, the outer members of said body being adapted to be secured to the inner side of a trousers-band, a suspender-end and a button projecting therefrom and adapted to have its shank passed between the central loop portions of said catch-body, substantially as specified.

698,457. SUSPENDERS AND TROUSERS CONNECTION. RICHARD T. CLARK, Columbus, Ohio. Filed Aug. 15, 1901. Serial No. 37,008. (No model.)

Claim.—In a suspender and trousers connection, the combination with the suspender-end, of button-catching plates having transverse openings adapted to receive the suspender-ends and a tongue 3 projecting rearwardly therefrom, said tongue adapted to be inserted through the longitudinal-opening of said suspender-ends and each of said plates having its lower end portion terminating in a bifurcated hook, substantially as specified.

698,458. MACHINE FOR FOLDING AND ROLLING CLOTH. BRAD COHEN, Philadelphia, Pa. Filed Mar. 5, 1901. Serial No. 35,173. (No model.)

Claim.—In a machine of the class described, the combination of a frame 2, an inclined triangular guide mounted on the frame 2 at one end thereof, the supplemental frame arranged at right angles to the frame 2 and located adjacent to and beneath the triangular guide, the inclined base arranged parallel and extending from a point adjacent to the apex of the triangular guide and located beneath the same, the horizontal arm extending from the lower end of the inclined base at one side of the frame and terminating short of the opposite side, the guide-roller 18 located beneath and in approximately the same vertical plane as the arm and the inclined base, the upper guide-roller 19 arranged in rear of the arm at a point above the guide-roller 18, and the separable winding device adapted to receive a board for the cloth, substantially as described.

698,459. COTTON-SEED PLANTER. ADAM S. OKE, Wilmerville, N. C. Filed July 14, 1901. Serial No. 35,382. (No model.)

Claim.—1. In a planter, the combination with a wheeled frame having a seedbox, of a disc carried to the frame and located in front of the seedbox, the rear portion of the disc having a throat which is open at its top and bottom and is projected beneath the discharge-opening of the seedbox to receive the seed therefrom, an opener carried by the front of the disc and a hollow depressing-gage carried by the rear portion of the disc beneath the throat thereof and in alignment with the opener and having an open top and an open rear end to receive and discharge the seed to the furrow.

2. In a planter, the combination with a wheeled frame having a seedbox, of a disc carried to the frame and located in front of the seedbox, the rear portion of the disc having a throat which is open at its top and bottom and is projected beneath the discharge-opening of the seedbox to receive the seed therefrom, a hollow depressing-gage carried by the rear portion of the disc beneath the throat thereof and having an open top and an open rear end to receive and discharge the seed to the furrow, a cross-bar carried by and projected at opposite sides of the disc, a substantially V-shaped flange embracing the front end of the disc and having its ends connected to the respective ends of the cross-bar, and an opener aligned in front of the depressing-gage and held between the cross-bar and the apex of the flange.

3. In a seed-planter, the combination with a seedbox, and a furrow-opener located in front thereof, of a depressing-gage located in rear of and aligned with the opener, and also aligned below the discharge-opening of the seedbox, and having its top open to receive the seed from the

box and also having its rear end open to deliver the seed to the furrow made by the furrow-opener.

4. In a seed-planter, the combination with a seedbox, and a furrow-opener located in front thereof, of a disc located between the box and the furrow-opener and having a rear throat portion located below the discharge-opening of the box and having its opposite inner walls converged inwardly and downwardly, and a depressing-gage located beneath and in close proximity to the forward portion of the throat and opening the bottom opening thereof as to receive seed therefrom.

5. In a cotton-seed planter, the combination with the seedbox and seed-roller, of a disc having the corners of its front ends diagonally recessed to present inclined shoulders, a V-shaped flange secured against the shoulders, and a cross-bar secured in recesses in the outer side of the disc and to which the outer ends of the flange are secured.

6. In a planter, the combination with the seedbox thereof, and a furrow-opener located in front of the box, of a disc located between the opener and the box and formed by a plurality of longitudinal members, the outer of which have their rear ends extended to form a throat located beneath the discharge-opening of the seedbox, a cross-bar projected at opposite sides of the disc members and forming a connection therebetween, and a substantially V-shaped flange embracing the front end of the disc and having its rear ends connected to the outer ends of the cross-bar.

7. In a planter, the combination with a seedbox, of a disc located below and in front of the seedbox and having a throat disposed below the discharge-opening of the seedbox to receive seed therefrom, a cross-bar let into the under side of the disc and projected at opposite sides thereof, a substantially V-shaped flange embracing the front of the disc and secured to the opposite ends of the cross-bar, and a furrow-opener held between the cross-bar and the apex of the flange.

8. In a cotton-seed planter, the combination with a supporting-frame, of spring-arms carrying a roller, a scraper connecting the rear ends of the arms, straps secured to the supporting-frame and having their outer ends formed into steps to coast with the spring-arms to limit vertical movement of the roller in one direction, and vertically-slotted links carried by the steps and loosely embracing the spring-arms to limit vertical movement of the roller in the opposite direction thereof.

9. In a planter, the combination with a supporting-frame, of spring-arms connected at their forward ends to the frame, a coverer carried by the free rear ends of the spring-arms, straps pendant from the frame, and elongated loop-shaped links arising from the straps and loosely embracing the free end portions of the respective spring-arms, the latter being capable of vertical movement within the links, and the lower ends of the straps lying in the paths of the upward movements of the arms and forming steps to limit said movements.

10. In a seed-planter, a disc comprising opposite longitudinal members, which have the lower portions of their ends notched and inclined outwardly and rearwardly, an intermediate member disposed between the opposite side members and terminated short of the rear ends thereof, the spaced rear end portions of the side members forming an open-ended throat, a cross-bar let into the lower edges of the side members and located between the throat and the forward end of the disc, a substantially V-shaped flange fitted to the forward ends of the side members and secured to the outer ends of the cross-bar, a furrow-opener held snugly between the forward end portions of the side members, the vertex of the flange and the intermediate front side of the cross-bar, and a depressing-gage carried by the under side of the disc and in communication with the lower open end of the throat.

698,460. SEWER-TRAP. JAMES CRAWFORD, Boston, Mass. Filed July 15, 1901. Serial No. 35,323. (No model.)

Claim.—The herein-described cover-trap, consisting of a pipe having in one end means for connecting it to the house-drain, a removable cover on said house end portion, a downwardly and laterally projecting trap-pipe leading to the cover end of the trap, the latter being arranged at one side of the house end portion and provided with a removable liquid-sealed cover substantially as set forth for the purpose set forth.

698,461. HEAD-BLOCK OR FOLLOWER. JAMES J. CROWLEY, Logan, Mont. Filed June 20, 1901. Serial No. 64,000. (No model.)

Claim.—1. A head-block or follower comprising a body portion, channelled wear and reinforcing plates embracing the ends of the body portion, channelled bearing-plates embracing the ends of the block and provided with elongated slots, pins passing through said slots and into the block movably connecting the bearing-plates to the block, and springs interposed between the block and bearing-plates to yieldingly hold the same against the walls of the press-chamber.

2. A head-block or follower comprising a body portion, strips upon the sides of the block and spaced to form grooves for the passage of the binding-wire, channelled bearing-plates embracing the ends of the block and strips, and provided with elongated slots, pins passing through said slots and into the block movably connecting the bearing-plates to the block, and springs interposed between the block and bearing-plates to yieldingly hold the same against the walls of the press-chamber.

3. A head-block or follower comprising a body portion formed in its side edges with notches, transverse strips upon the sides of the block and spaced to form grooves for the passage of the binding-wire, channelled wear and reinforcing plates embracing the ends of the block and interposed between the same and strips and provided with openings registering with said notches, channelled bearing-plates embracing the ends of the block and strips and movably mounted upon the block, and springs seated in said notches and projecting through the openings in the reinforcing-plates and bearing against said bearing-plates.

698,462. PROCESS OF MAKING ALKALINE CYANIDE. JAMES D. DARLINS, Philadelphia, Pa., assignor to Harrison Bros. & Co., Incorporated, Philadelphia, Pa., a Corporation of Pennsylvania. Filed May 27, 1901. Serial No. 66,157. (No specimens.)

Claim.—The process of producing pure alkaline cyanide, which consists in subjecting alkaline acid to the action of carbon and nitrogen under the influence of heat, whereby cyanized charcoal is produced; and subjecting this cyanized charcoal to the action of ammonia-gas and alkali metal under the influence of heat, whereby the carbon remaining in the cyanized charcoal is converted into cyanide, substantially as described.

698,463. METHOD OF MAKING CYANIDE. JAMES D. DARLINS, Philadelphia, Pa., assignor to Harrison Bros. & Co., Incorporated, Philadelphia, Pa., a Corporation of Pennsylvania. Filed July 20, 1901. Serial No. 70,004. (No specimens.)

Claim.—The process of producing pure alkaline cyanide, which consists in subjecting carbon and alkaline acid to the action of nitrogen and simultaneously subjecting the excess of carbon to the action of alkali metal and ammonia, all under the influence of heat, substantially as described.

698,464. METHOD OF MAKING ALKALINE CYANIDE. JAMES D. DARLINS, Philadelphia, Pa., assignor to Harrison Bros. & Co., Incorporated, Philadelphia, Pa., a Corporation of Pennsylvania. Filed Oct. 6, 1901. Serial No. 77,000. (No specimens.)

Claim.—The process of producing pure alkaline cyanide, which consists in subjecting alkaline acid to the action of carbon and nitrogen under the influence of heat, whereby cyanized charcoal is produced; and subjecting this cyanized charcoal to the action of alkaline acid under the influence of heat, whereby the carbon remaining in the cyanized charcoal is converted into cyanide, substantially as described.

698,465. HOISTING APPARATUS. DAVID E. DARRIN, New York, and WILLIAM E. DOLLAR, Buffalo, N. Y., assignors to Howard Iron Works, a Corporation of New York. Filed Dec. 18, 1900. Renewed Mar. 7, 1902. Serial No. 97,000. (No model.)

Claim.—1. In apparatus of the character described, the combination with the gate or gates, of a controller for the gate-operating mechanism.

Claim.—1. In a device of the character described, a positive member firmly representing an operative device having a known function and provided with a movable element, an operative or active member, and connections between the movable element of the false member and the operative or active member for actuating the latter.

2. A device of the character described comprising a vessel having a false spigot including a movable member, and a separate water-ejecting apparatus operably connected with the movable member for control thereby.

3. The combination with a vessel having a movable member, of means for ejecting water from the vessel and controlled by actuation of the movable member in one direction, and a detouring mechanism controlled by return movement of the movable member.

4. The combination with a vessel having a movable member, of a mechanism disposed to eject water from the vessel, means for holding said mechanism inoperative, means connected with the movable member for releasing the holding means when the movable member is actuated in one direction, and a detouring mechanism operable by return movement of the movable member.

5. The combination of a car, a vertically-moving gate, spring-balls carried thereby and adapted to engage the elevator-shaft, a gate-holding rope connected to said spring-balls and adapted to withdraw the same and raise said gate, a controlling device comprising a controller for the gate-holding mechanism and a controller for the elevator-hoisting mechanism, a spring-bolt in the shaft adapted to engage the elevator-controller when the same is in position of rest, a cam on said gate adapted to engage and withdraw said last-named spring-bolt when the gate is closed, hoisting means for the elevator and the gates, and connections between the same and the elevator and gate-holding rope respectively, substantially as described.

698,466. AUTOMATIC WATER-COOLER FOR INITIATING FUEL-FIRES. ROBERT DE MOULIN and OLIVIER S. DE MOULIN, Greenville, N. C. Filed Mar. 11, 1901. Serial No. 60,007. (No model.)

Claim.—1. A hydrocarbon-oil burner having a combustion-chamber subdivided by a flame-plate forming bottom and top inlet and outlet passages in communication at one end of the chamber, an oil-reservoir in communication with the inlet-passage at the other end of the chamber, and a head guarding said inlet-opening and partially overhanging said reservoir for regulating the lower draft of air through the said inlet-passage, substantially as and for the purpose set forth.

2. A hydrocarbon-oil burner comprising a base having a trough forming the lower portion of a combustion-chamber, a cover closing the trough and forming the upper portion of the combustion-chamber, a partition subdividing said chamber to form upper and lower passages in communication at one end and provided, respectively, at the other end with an inlet and outlet, an oil-pan resting upon the base adjacent to said inlet, and a head or deflector for conducting the induced air and the products of combustion from the oil-pan to said inlet, the said parts being detachably connected, substantially as described.

3. A hydrocarbon-oil burner having a combustion-chamber divided by a flame-plate to form inlet and outlet passages located one above the other, said passages being in communication at one end of the chamber and having their inlet and outlet openings located at the opposite end of the chamber, an oil-reservoir, and a head partially overhanging the oil-reservoir for conducting the air and products of combustion therefrom to the inlet-opening of said inlet-passage, substantially as and for the purpose specified.

698,467. OIL-BURNER. BENJAMIN S. DUYER, Lima, Ohio. Filed July 15, 1901. Serial No. 63,000. (No model.)

4. A hydrocarbon-oil burner comprising a base having a trough forming the lower portion of a combustion-chamber, a cover closing the trough and forming the upper portion of the combustion-chamber, and a partition forming a flame-plate and separating said lower and upper portions of the chamber to form inlet and outlet passages, said passages being in communication at one end of the chamber and having their inlet and outlet openings at the opposite end of the chamber, substantially as described.

698,468. HENRY OSWALD BAKER, Cincinnati, Ohio. Filed Sept. 26, 1901. Serial No. 73,691. (No model.)

Claim.—1. A hinge comprising two parts or members one of which has two guides and the other a pin or stud adapted to engage with each guide, one of said pins or studs having a lag or keeper adapted to detachably and removably interlock and engage its adjacent guide.

2. A hinge comprising two parts or members, one of which has a guide and the other a corresponding pin or stud having a lag or keeper thereon adapted to engage said guide and hold the parts of the hinge in proper relative position to each other, and means for pivoting the two parts of the hinge together.

3. A hinge comprising in its construction two members adapted to be respectively secured to a box and its cover, the box member being provided with guide-ribs, the one being concentric to the other, and the cover member having guide-pins each provided with a lag or keeper and adapted to be seated in, take over and engage the edges of the respective guide-ribs of the box member.

698,469. ADDRESSING ATTACHMENT FOR TYPE-WRITERS. GEORGE L. DOWNEY, Cincinnati, Ohio. Filed Oct. 1, 1900. Serial No. 31,671. (No model.)

Claim.—1. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a spacing and indenting device adapted to be engaged by said carriage and held in travel and to automatically space the platen-roll, substantially as specified.

2. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a spacing and indenting device located at the initial end of the carriage travel adapted to be engaged thereby, means on said spacing and indenting device and carriage adapted to automatically space and indent the platen, substantially as specified.

3. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a spacing and indenting device located at the initial end of carriage travel adapted to be engaged thereby to revolve the platen, the said spacing and indenting device having two or more different indentation-steps, said steps adapted to be successively presented to said carriage, substantially as specified.

4. In combination with the carriage of a type-writer, a platen-roll journaled thereon, having an extended axle on the initial end of the carriage travel, a spacing and indenting device located at the initial end of the carriage travel, the said spacing and indenting device having walls with notches of varying depth and pitch and a finger on said extended platen-axle adapted to engage into said notches whereby the initial position of the carriage is determined and the platen revolved, substantially as specified.

5. In combination with the carriage of a type-writer, a platen-roll journaled thereon having an extended axle on the initial end of the carriage travel, a spacing and indenting device having notches of varying depth and pitch, located at the initial end of the carriage travel, a projection on the said extended axle adapted to engage into said notches whereby the initial position of the carriage is determined and the platen revolved, substantially as specified.

6. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a spacing and indenting device located at the initial end of carriage travel having notches formed therein of varying depth in a horizontal plane, and inclined in a vertical plane, a projection on the platen-roll adapted to successively engage into said notches when the carriage is revolved to its initial position, substantially as specified.

7. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a tension device exerting pressure on the carriage to the right, mechanism actuated by the keyboard adapted to feed the carriage from left to right, type arranged in the normal legible position in the machine, a spacing and indenting device, and a shifting-lever on the said carriage adapted to engage said carriage with said spacing and indenting device whereby the platen-roll is automatically spaced and indented, substantially as specified.

8. In combination with the carriage of a type-writer, a tension device exerting pressure on the carriage to the platen-roll journaled on said carriage, mechanism actuated by the keyboard adapted to feed the carriage from left to right, an extended axle at the initial end of the platen-roll, a spacing and indenting device located opposite the said extended axle within the path of carriage travel, the said spacing and indenting device having notches of varying depth and pitch, a finger on the extended platen-axle adapted to engage into said notches whereby the platen-roll is spaced and indented, and type whereby the characters are horizontally printed inversely upon a transcript-sheet, substantially as specified.

9. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a spacing and indenting device located at the initial end of the path of travel of the carriage, a shifting-lever adapted to throw said carriage in engagement with said spacing and indenting device to automatically space and indent the platen-roll, a supplemental frame mounted on the carriage, a supporting and receiving roll journaled in said frame and means for revolving said roll, substantially as specified.

10. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a tension device exerting pressure on the carriage to the right, mechanism actuated by the keyboard adapted to feed the carriage from the left to right, type adapted to be inversely printed upon a transcript-sheet, a supplemental frame mounted on the carriage, a supporting and receiving roll journaled in the frame and a power-transmitter between one of said rolls and the platen-roll, a spacing and indenting device located at the initial end of the carriage travel, a projection on the said platen-roll adapted to engage the spacing and indenting device to revolve the platen-roll and determine its initial position, and means for shifting said carriage toward said spacing and indenting device, substantially as specified.

11. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a spacing and indenting device at the initial end of carriage travel, a cam provided with notches whose depth determines the indentation of the platen-roll and whose pitch determines the interlineal space, a projection on the platen-roll adapted to engage said cam, and means for shifting the carriage toward the spacing device, substantially as specified.

12. In combination with the carriage of a type-writer a platen-roll journaled thereon, a spacing and indenting device at the initial end of carriage travel having cylindrical walls extended toward the platen-roll, duplicate notches diametrically opposite each other in the peripheral walls of said spacing device whose depth determines the degree of platen indentation, and whose pitch determines the interlineal spacing of said platen-roll, a projection on said platen-roll adapted to simultaneously engage the duplicate notches, and means for shifting said carriage toward the spacing and indenting device, substantially as specified.

13. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a spacing and indenting device located at the initial end of carriage travel having notches of varying depth and pitch, a projection on said platen adapted to engage said notches, means for successively presenting the different notches to said projection, and a lever for shifting said carriage toward the spacing and indenting device, substantially as specified.

14. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a spacing and indenting device located at the initial end of the carriage travel, the said spacing and indenting device having notches of varying depth and pitch presented toward the platen-roll, a finger on said platen-roll adapted to engage into said notches, whereby the platen-roll is rotated and the finger successively presented to a different notch at each revolution, substantially as specified.

15. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a spacing and indenting device located at the initial end of the carriage travel, the said spacing and indenting device having notches of varying depth and pitch presented toward the platen-roll, a finger on said platen-roll adapted to engage into said notches, whereby the platen-roll is rotated and the finger successively presented to a different notch at each revolution, substantially as specified.

16. In combination with the carriage of a type-writer, a platen-roll journaled thereon, a spacing and indenting device located at the initial end of the carriage travel, the said spacing and indenting device having notches of varying depth and pitch presented toward the platen-roll, a finger on said platen-roll adapted to engage into said notches, whereby the platen-roll is rotated and the finger successively presented to a different notch at each revolution, substantially as specified.

journaled thereon, a tension device exerting pressure on the carriage to the right, mechanism actuated by the keyboard adapted to feed the carriage from the left to right, type adapted to be inversely printed upon a transcript-sheet, a supplemental frame mounted on the carriage, a supporting and receiving roll journaled in the frame and a power-transmitter between one of said rolls and the platen-roll, a spacing and indenting device located at the initial end of the carriage travel, and means for shifting said carriage toward said spacing and indenting device, substantially as specified.

16. In combination with the carriage of a type-writer, a platen journaled thereon, a tension device exerting pressure to the right, mechanism actuated by the keyboard to feed the carriage from left to right, and an automatic indenting device located in the initial end of the carriage travel and actuated thereby, substantially as specified.

17. In combination with the carriage of a type-writer, a platen journaled thereon, a tension device exerting pressure to the right, mechanism actuated by the keyboard to feed the carriage from left to right, means mounted on the carriage for feeding and receiving a transcript-sheet to and from the platen, and an indenting device located in the initial end of the carriage travel and actuated thereby, substantially as specified.

698,470. FASTENING DEVICE. ALVIN L. BRACE, New York, N. Y. Filed Sept. 12, 1901. Serial No. 73,199. (No model.)

Claim.—1. A device of the character specified comprising an apertured plate of ductile material which is adapted to be bent so substantially the lines of the aperture therein so that the walls of said aperture will constitute binding-jaws.

2. A device of the character specified comprising a plate of ductile metal which has an elongated band-receiving aperture therein, the walls of said aperture being curved and adapted to constitute binding-jaws for securing the band to the plate and means carried by said plate and formed integral therewith for permanently securing the opposite end of the band to said plate.

3. In a device of the character specified, the combination of a clamp formed of a single piece of ductile metal and provided with clamping-ears which are adapted to permanently secure said clamp to one end of a band and having an elongated perforation therein, the walls of which perforation are adapted to form plumping-jaws and a band permanently secured to the clamp by the clamping-ears and its free end adapted to pass through the elongated aperture in said clamp and be secured therein when a portion of the clamp carrying one of the jaws is bent from its initial position.

698,471. DETACHABLE BULLET-FLUE. JULIAN F. BRACE, Troy, N. Y. Original application filed Mar. 26, 1901, Serial No. 32,394. Divided and this application filed Nov. 8, 1901. Serial No. 31,167. (No model.)

Claim.—1. In a boiler, the combination with a fire-sheet, of a flue having rigidly secured to one end an inwardly-tapering conical sleeve, and a packing ring or bushing of relatively soft material, but of high fluidity,

interposed and pressed between the said sleeve and its seat in the fire-sheet, which packing ring or bushing closely fits said conical sleeve and tapers in the same direction therewith, both at its interior and exterior surfaces, substantially as described.

2. In a boiler, the combination with the fire-sheet 1 having the inwardly-tapered end 2, of the flue 3 having the inwardly-tapered conical sleeve 4 screw-threaded thereon, and the tapered packing ring or bushing 5 of copper, pressed between said sleeve 4 and end 2, said ring or bushing 5 closely fitting said sleeve and tapering in the same direction therewith, both at its exterior and interior surfaces, substantially as described.

698,472. AUTOMATIC GUN. LOUIS L. DIXON, Washington, D. C. Assignor to Wright-Battery Gun and Ammunition Company, New York, N. Y., a Corporation of New Jersey. Filed Aug. 24, 1897. Serial No. 342,298. (No model.)

Claim.—1. In an automatic gun, the combination with a gun-casing, a spindle journaled concentric with said casing, a plurality of barrels having rearwardly-extending heads grouped around said spindle and rotating therewith, guides mounted on said spindle and allowing said barrels to move longitudinally relative to said spindle, and interlocking cam-surfaces between said barrels and said gun-casing, whereby as each barrel is fired, the said barrel recoils and rotates said spindle, substantially as described.

2. In an automatic gun, the combination with a gun-casing, a spindle journaled concentric with said casing, a plurality of barrels having rearwardly-extending heads grouped around said spindle and rotating therewith, guides mounted on said spindle and allowing said barrels to move longitudinally relative to said spindle, and interlocking cam-surfaces between the exterior of said barrels and the interior of said casing, whereby said barrels cause said spindle to rotate about its axis as each barrel recoils, and means for loading cartridges into said barrels for firing the gun, substantially as described.

3. In an automatic gun, the combination with a gun-casing, a spindle journaled concentric with said casing, a plurality of barrels having rearwardly-extending heads grouped around said spindle and rotating therewith, guides mounted on said spindle and allowing said barrels to move longitudinally relative to said spindle, and interlocking cam-surfaces between the exterior of said barrels and the interior of said casing, whereby said barrels are caused to rotate said spindle about its axis as the barrel recoils, and means operated by the rotation of the said barrel about said spindle for feeding the cartridges to and for ejecting the same from the said barrels, and automatically-operated means for firing said cartridges, substantially as described.

4. In an automatic gun, the combination with a group of barrels adapted to rotate about a common axis, and each provided with a rear-

wardly-projecting heel with slots therein, of a breech-block mounted in said heel and legs or projections engaging in said slots, means operated by the check of discharge for rotating said group of barrels about said common axis, and for moving said breech-block in said slots from the open to the closed position and vice versa, means for loading said barrels, a spring-operated firing-pin mounted in each of said breech-blocks, and means for automatically cocking and releasing the same substantially as described.

5. In an automatic gun, the combination with a group of barrels adapted to rotate about a common axis, and each provided with a rearwardly-projecting heel with slots therein, of a breech-block mounted in said heel with legs or projections engaging in said slots, means operated by the check of discharge for rotating said group of barrels about said common axis and for moving said breech-block in said slots from the open to the closed position and vice versa, means also operated by the check of discharge for loading said barrels, a spring-operated firing-pin mounted in each of said breech-blocks, and means for automatically cocking and releasing the same, substantially as described.

6. In an automatic gun, the combination with a group of barrels adapted to rotate about a common axis but to recoil parallel to said axis, and each provided with a rearwardly-projecting heel with slots therein, of a breech-block mounted in said heel with legs or projections engaging in said slots, means operated by the recoil of each barrel for rotating the said group of barrels through a given angle about said common axis, and for moving said breech-block in said slots from the open to the closed position and vice versa, means for loading said barrels, a spring-operated firing-pin mounted in each of said breech-blocks, and means for automatically cocking and releasing the same, substantially as described.

7. In an automatic gun, the combination with a group of barrels adapted to rotate about a common axis but to recoil parallel to said axis, and each provided with a rearwardly-projecting heel with slots therein, of a breech-block mounted in said heel with legs or projections engaging in said slots, means operated by the recoil of each barrel for rotating the said group of barrels through a given angle about said common axis, and for moving said breech-block in said slots from the open to the closed position and vice versa, means operated by the recoil for loading said barrels, a spring-operated firing-pin mounted in each of said breech-blocks, and means for automatically cocking and releasing the same, substantially as described.

8. In an automatic revolving cannon the combination with a gun-casing, a spindle journaled concentric with said casing, a plurality of barrels grouped around said spindle and adapted to rotate therewith and also to move longitudinally relative to said spindle, each barrel being provided with a rearwardly-projecting heel with slots therein, of a breech-block mounted in said heel with legs or projections engaging in said slots, a spring-operated firing-pin mounted in each of said breech-blocks, intersecting cam-surfaces provided between said barrels, said breech-block, said firing-pin and said gun-casing, whereby as each barrel is fired, the said barrel recoils and rotates said spindle, and the breech-block is brought from the closed to the open position and the firing-pin is operated, and means for loading cartridges into said barrels, substantially as described.

9. In an automatic revolving cannon the combination with a gun-casing, a spindle journaled concentric with said casing, a plurality of barrels grouped around said spindle and adapted to rotate therewith, and also to move longitudinally relative to said spindle, each barrel being provided with a rearwardly-projecting heel with slots therein, of a breech-block mounted in said heel with legs or projections engaging in said slots, a spring-operated firing-pin mounted in each of said breech-blocks, intersecting cam-surfaces provided between said barrels, said breech-block, said firing-pin and said gun-casing, whereby as each barrel is fired, the said barrel recoils and rotates said spindle, the breech-block is brought from the closed to the open position and the firing-pin is operated, and means operated by the rotation of the said barrels about said spindle for feeding the cartridges to and for ejecting the same from the said barrels, substantially as described.

10. In an automatic revolving cannon the combination with a gun-casing, a spindle journaled concentric with said casing, a plurality of barrels grouped around said spindle and adapted to rotate therewith, and also to move longitudinally relative to said spindle, each barrel being provided with a rearwardly-projecting heel with slots therein, of a breech-block mounted in said heel with legs or projections engaging in said slots, a spring-operated firing-pin mounted in each of said breech-blocks, intersecting cam-surfaces provided between said barrels, said breech-block, said firing-pin and said gun-casing, whereby as each barrel is fired, the said barrel recoils and rotates said spindle, the breech-block is brought from the closed to the open position, and the firing-pin is operated, and means operated by the rotation of the said barrels about said spindle for feeding the cartridges to and for ejecting the same from the said barrels, substantially as described.

11. In an automatic revolving cannon, the combination with a gun-casing provided with cam-grooves therein, a spindle journaled concentric

with said casing a plurality of barrels grouped around said spindle and adapted to rotate therewith and also to move longitudinally relative to said spindle, each barrel being provided with a rearwardly-projecting heel with slots therein, of a breech-block mounted in said heel with legs or projections engaging in said slots, a spring-operated firing-pin mounted in each of said breech-blocks, legs on said barrels, on said breech-blocks and on said firing-pins engaging in said cam-grooves in said gun-casing, whereby as each barrel is fired, the said barrel recoils and rotates said spindle and operates said breech-block and said firing-pin, substantially as described.

12. In an automatic revolving cannon, the combination with a gun-casing provided with cam-grooves on the interior thereof, and a spindle journaled in said casing, of a plurality of barrels grouped about said spindle, and adapted to move longitudinally relative thereto, each barrel being provided with a rearwardly-projecting heel with slots therein, of a breech-block mounted in said heel with legs or projections engaging in said slots, a spring-operated firing-pin mounted in said breech-block, legs on the exterior of said barrels, on said breech-blocks and on said firing-pins engaging the cam-grooves in said casing, whereby said barrels cause said spindle to rotate about its axis as the barrel recoils and said breech-block and firing-pin are operated, and means operated by the recoil for loading cartridges into said barrels, substantially as described.

13. In an automatic revolving cannon the combination with a gun-casing provided with journal-bearings and cam-grooves, of a spindle journaled in said bearings, a plurality of barrels grouped around said spindle and adapted to rotate therewith and also to move longitudinally relative to said spindle, each barrel being provided with a rearwardly-projecting heel with slots therein, of a breech-block mounted in said heel with legs or projections engaging in said slots, a spring-operated firing-pin mounted in said breech-block, legs on the exterior of said barrels, on said breech-blocks and on said firing-pins engaging the cam-grooves in said casing, whereby said barrels cause said spindle to rotate about its axis as the barrel recoils and said breech-block and firing-pin are operated, and means operated by the recoil for loading cartridges into said barrels, substantially as described.

14. In an automatic revolving cannon, the combination with a substantially cylindrical shell or casing provided on the inner surface thereof with two cam-grooves of varying pitch, the front cam-groove being essentially V-shaped when developed, and the rear cam-groove having a small part of its length parallel to one of the sides of the V of the front groove and then approaching said side at a slight inclination, with a slight elevation in one portion of the said rear groove, of a spindle journaled in the center of the cylindrical shell, longitudinally-movable barrels grouped about said spindle and each having a rearwardly-extending heel with a longitudinal slot therein and slots transverse to said longitudinal slot, a leg or projection on each of said barrels engaging in the front cam-groove, and a breech-block mounted in rear of the cartridge-chamber, and having legs adapted to engage in said slots, and also a leg adapted to engage in said rear cam-groove, substantially as described.

15. In an automatic revolving cannon, the combination with a substantially cylindrical shell or casing provided on the inner surface thereof with two cam-grooves of varying pitch, the front cam-groove being essentially V-shaped when developed, and the rear cam-groove having a small part of its length parallel to one of the sides of the V of the front groove and then approaching said side at a slight inclination, with a slight elevation in one portion of the said rear groove, and a cam-rod also provided on the interior of the casing, of a spindle journaled in the center of the cylindrical shell, longitudinally-movable barrels grouped about said spindle and each having a rearwardly-extending heel with a longitudinal slot therein and slots transverse to said longitudinal slot, a leg or projection on each of said barrels engaging in the front cam-groove, and a breech-block mounted in rear of the cartridge-chamber, and having legs adapted to engage in said slots, and also a leg adapted to engage in said rear cam-groove, and a spring-operated firing-pin having a cam-rod adapted to engage said cam-rod, substantially as described.

898,478. NARROW-TOOTH FASTENER. JAMES F. DOWDY, Averyville, Ill., assignor to Kingston Flow Company, Peoria, Ill., a Corporation of Illinois. Filed May 4, 1901. Serial No. 54,817. (No model.)

Claim.—1. In a narrow-tooth fastener the combination of the U-bar A forming the support for the narrow-tooth, the tooth B seated on the said bar at right angles to its length, the middle C also in form of a U the same being seated to straddle the tooth, the extension D thereof

extending into the hollow of the bar A, an aperture in each extremity D, a T-bolt F having its two ends projecting through the bottom of the said bar and each of its upper extremities engaging with the aperture G in the said extremities D, said T-bolt adapted, when its nut is tightened, to draw the middle down to clamp the tooth to the U-bar as set forth.

2. In a narrow-tooth fastener, the combination of the U-bar A, the narrow-tooth B seated therein across the flanks thereof, the middle C seated upon the tooth, the extension D on the middle the same depending within the U-bar, the bolt F projecting through the bottom of said bar, the extension H H on the top of the bolt in the form of a semicircle, apertures G in the extension D for receiving the said extensions H H, the relation of the parts being such that when the bolt is drawn down by means of its nut the extension D will be drawn toward each other by reason of the oppositely-inclined extensions H to tightly lock the tooth B as set forth.

3. In a narrow-tooth fastener, the combination of the U-bar A, the tooth B seated across the flanks of the said bar at right angles thereto, the middle C straddling the said tooth, the extension D of said middle, the same extending into the recess of the U-bar, an aperture in each extremity of the extension D, a T-bolt F passing through the bottom of the U-bar, the upper extremities H thereof lying within the said apertures and arranged whereby when the bolt is tightened the middle will be drawn down and the extensions D thereof brought toward each other as set forth, and the projections G on the middle for preventing the spreading of the flanks of the said U-bar as set forth.

4. A tooth-fastener for harrows comprising a U-shaped support for the tooth, the tooth lying against the support on the extension thereof and at right angles to their length, a middle for straddling the tooth, said middle projecting downward at each side of the tooth, part thereof extending into the hollow of the U-bar and having an aperture in each, a part extending outside of each extremity as shown, a T-bolt located between the extensions of the middle within the U-bar the arms thereof engaging the apertures of the middle extensions substantially as set forth, the bolt portion of said T-bolt passing through the U-bar and held by a nut, the arms of said bolt extending downward at an angle through the apertures of the middle extensions whereby when the bolt is tightened the middle extensions are made to move up the angled extensions and approach each other as described and whereby also, the outside projections of the middle are drawn down outside the U-bar and prevent the spreading of the extensions of the same.

898,474. WATER-COOLED VALVE. HERMANN E. BERN, Wurzburg, Germany, assignor to The Firm of Vereinigte Maschinenfabrik Augsburg and Maschinenbaugesellschaft Murnberg A. G., Wurzburg, Germany. Filed Oct. 25, 1901. Serial No. 79,946. (No model.)

Claim.—1. In a valve, the combination of a hollow body having a spiral groove therein, an intermediate plate closing said groove, said plate having a similar spiral groove in its base, means for closing said similar groove, a part for establishing communication between the two spiral grooves, and means for causing a flow of cooling liquid through the said spiral grooves, substantially as described.

2. In a valve the combination of a hollow body having a spiral groove therein extending from the center to the rim in a plane parallel to the valve-face, an intermediate plate closing said groove, said plate having a spiral groove and having a similar spiral groove in the opposite face, a hollow valve-stem having a smooth face to close the lower spiral groove and adapted to screw into the hollow valve-body, the interior of the hollow stem being in communication with the center of the lower channel, a field-feed pipe within the said hollow stem in communication with the center of the upper spiral channel and a part to establish communication between the outer ends of the said upper and lower channels substantially as described and for the purpose specified.

898,475. FIRE-SHUTTER. FREDERICK H. BROWN, Columbus, Ohio, assignor, by mesne assignments, to Edward Black, Plain City, Ohio. Filed Nov. 5, 1900. Serial No. 38,463. (No model.)

Claim.—1. In a fire-shutter, the combination with a spring-actuated roller comprising a journaled cylindrical body 5, bearing-shafts 12 and 13 and a spring having one end connected with said shaft 12 and its remaining end connected with the cylindrical roller, of a toothed wheel 16 on the shaft 12, a pivoted pawl-bar having a finger adapted to project into a tooth-space of the wheel 16 and a detachable connection between the pawl-bar and a fixed part, substantially as specified.

2. In a fire-shutter, the combination with a journaled spring-actuated roller and a sectional fire-shutter adapted to be rolled thereon, said roller comprising a cylindrical body 5, and bearing-shafts and a spring connecting one of said shafts with said roller-body, of a toothed tension-wheel on said spring-shaft, a pivoted pawl adapted to engage said toothed wheel, a bolt connection between said pawl and a fixed part, a spring about the bolt and a flexible nut on said bolt, substantially as specified.

898,476. LASTING-MACHINE. ERNEST H. BERN, Berlin, Germany, assignor to Ernst Berner, Berlin, Germany. Filed Apr. 19, 1901. Serial No. 54,874. (No model.)

Claim.—In a lasting-machine, the combination with the last-holder and the upper-support adjacent thereto, of a horizontally-disposed sliding plate supported upon said upper-support, a pair of horizontally-disposed upper-jaws pivoted to said sliding plate, a cam-disk located beneath the rear ends of said jaws, a cam-groove in said disk, links connecting said disk with the ends of said upper-jaws, and a pin carried by the plate engaging the cam-groove in the disk, substantially as described.

898,477. CLOTHING-LINE REEL. EDWARD I. BURNHAM, Quincy, Mass. Filed Mar. 26, 1901. Serial No. 54,394. (No model.)

Claim.—1. In a clothing-line reel, a bar or housing, a reel mounted on a shaft and located therein, a pin on the outside of the bar and connected to said reel to rotate the same, a slidably-mounted drive-gear constantly in mesh with the pinion, a spring to maintain said gear in its operative position, and a pawl cooperating with the ratchet, said pawl having a leg thereon which is adapted to engage the drive-gear and hold the same out of mesh with the pinion when the pawl is in its operative position.

2. In a clothing-line reel, a bar or housing, a reel mounted on a shaft and located therein, the end of the shaft projecting through the bar or housing, a pinion on the projecting end of the shaft, a ratchet inter-

gral throwwith, a slidably-mounted drive-gear normally in mesh with the pinion, a pawl cooperating with the ratchet, said pawl having a lug thereon which when the pawl is in its operative position with respect to the ratchet is adapted to engage the inner face of the drive-gear and hold the same out of mesh with the pinion, and means for automatically throwing the drive-gear into mesh with the pinion when the pawl is drawn into operative position.

3. In an apparatus of the class described, a series of open hooks adapted to support a clothes-line, combined with a clothes-line reel inclosed in a box or housing, a pinion on the outside of the box connected to the reel, a shaft projecting from the side of the box, a drive-gear slidably mounted thereon and normally in mesh with the pinion but adapted to be disconnected therefrom whereby the drive-gear may be thrown out of engagement with the pinion when it is desired to unwind the reel and means to hold said drive-gear in either of its adjusted positions.

4. In apparatus of the class described, a box or housing adapted to be secured to a support and having a hinged cover, a reel inclosed in said box, a pinion on the outside of the box and connected to the reel, a shaft projecting from the outside of the box, a driving-gear slidably mounted upon said shaft and adapted to be made to mesh with or be disconnected from the pinion, means to hold the driving-gear in either of its adjusted positions, combined with a series of open hooks adapted to support a clothes-line, one of said hooks being connected to the support above the box whereby the clothes-line when in place extends through the open upper end of the box up to said last-mentioned open hook and then to another hook of the series.

5. In a clothes-line reel, a box inclosing a reel, a casing on the outside of the box, said casing having an aperture to receive and form a bearing for the end of the shaft of the reel, a combined pinion and ratchet fast on said shaft, a stud integral with the casing, a drive-gear on said stud and meshing with the pinion, a pawl pivoted to the casing and co-operating with the ratchet, and means whereby the drive-gear may be disconnected from or may be made to mesh with the pinion.

698,478. COMBINED HOT BLAST AND SMOKE-CONSUMER. JOHN E. BRILLMAN, Indianapolis, Ind. Filed Dec. 15, 1901. Serial No. 94,181. (No model.)

Claim.—1. In a combined hot blast and smoke-consumer for ranges and cooking-stoves, a pipe having a curved end which engages with an ingrain-bowl fixed on the surface of the range, the said bowl forming an ingrain to the pipe which pipe is composed of segments having overlapping edges which are held together by the transverse bolts 19, integral flanges at the point of curvature which flanges form a bearing for the pipe and whereby the said pipe is secured to the range or stove by bolts, secondary flanges at the upper end of the curvature of the pipe which flanges rest against the under side of the range-top, bolts passing vertically through the said flanges, the range-top and feet of the bowl, whereby the parts are securely held together, substantially as shown and for the purposes set forth.

2. In a combined hot blast and smoke-consumer for ranges and cooking-stoves, a pipe fixed to the range which extends into the fire-box thereof, the rear end of the pipe being curved and engaging with a bowl which forms the ingrain for the pipe, a plate carrying slots secured in the upper portion of the bowl, a secondary overlying shifting plate carrying slots which register with the slots in the under plate, the combined plate forming a damper for regulating the inflow of air, integral lugs on the under plate of the damper, each of which carries an aperture, the rear lugs forming a bearing for an ornamental base, while the front lugs pro-

vide a pivotal bearing for a swinging bracket, whereby a means for shifting said bracket over the superheated portion of the range is presented, substantially as shown and for the purposes set forth.

698,479. WINDMILL MECHANISM. MYRON W. ELLIOTT, JR., Beloit, Wis., assignor to Fairbanks, Morse & Company, Chicago, Ill., a Corporation of Illinois. Filed Apr. 19, 1901. Serial No. 94,054. (No model.)

Claim.—1. An improvement in windmill mechanism comprising a journal-casting, a wheel-hub constructed to act as a brake-spider, a brake-ring longitudinally movable upon said journal-casting, a lever for moving said brake-ring, a fulcrum-bracket for said lever fixed relative to said journal-casting, and means for imparting movement to said lever when the mill is started, said fulcrum-bracket preventing a rotation of the brake-ring without a strain on said operating means, substantially as described.

2. An improvement in windmill mechanism comprising a journal-casting, a wheel-hub constructed to act as a brake-spider, a brake-wheel longitudinally movable upon said journal-casting and provided with a collar having a slotted opening, a projection upon said journal-casting passing through said slotted opening to prevent rotation of said collar and brake-ring, and means operatively connected to said projection for imparting longitudinal motion to said brake-ring, substantially as described.

3. An improvement in windmill mechanism comprising a pivot-pipe, a pump-rod operating therein, a slot in one side of said pivot-pipe, a pitman for actuating said pump-rod, a connection between said pitman and said pump-rod passing through said slot, and a guide for said pump-rod within said pivot-pipe, said guide being external relatively to the pump-rod, substantially as described.

4. An improvement in windmill mechanism comprising a pivot-pipe, a pump-rod operating therein, a slot in one side of said pivot-pipe, a pitman for actuating said pump-rod, a connection between said pitman and said pump-rod passing through said slot, and a guide for said pump-rod within said pivot-pipe formed by bending a portion of the walls of the pipe forward, substantially as described.

698,480. MECHANICAL MUSICAL INSTRUMENT. CHARLES L. BRIDGES, Cranford, N. J., assignor to the Aeolian Co., New York, N. Y., a Corporation of Connecticut. Filed Dec. 2, 1901. Serial No. 94,400. (No model.)

Claim.—1. In a mechanical musical instrument the combination of a casing having a resonator, music-aperture and a trucker-board located in said resonator, a pair of supports also provided in said resonator and extending longitudinally thereof, and a transparent cover having two opposite edges in engagement with said supports and adapted to be slid therealong.

2. In a mechanical musical instrument the combination of a casing having a resonator, music-aperture and a trucker-board located in said resonator, a pair of grooved supports also provided in said resonator and extending longitudinally thereof, a transparent cover having two opposite edges fitting

In the groove of said supports and means for retaining said edges in the said groove.

698,481. BOX-ASSEMBLING MACHINE. HANCOCK BISHOP, Chicago, Ill. Filed Sept. 12, 1900. Serial No. 93,741. (No model.)

Claim.—An egg-case having its sides and bottom made of a strip of wood-pulp board scored transversely on the inside to form corners which are preferably smooth externally, the said strip being attached to transverse parts which form the ends of the case and a partition in the case and the box being further provided with external reinforcing-strips that extend continuously around its upper edge, making smooth and perfect corners where they join substantially as set forth.

698,482. BOX-ASSEMBLING MACHINE. HANCOCK BISHOP, Chicago, Ill. Filed Mar. 15, 1901. Serial No. 91,200. (No model.)

Claim.—1. A box-assemblying machine provided with a U-shaped stationary frame having ends on its uprights, a cradle having transverse members in said ends and provided with end clamping-plates, means for adjusting said plates relatively to each other and two series of intermediate clamping-plates, the plates of each series being connected by toggle-levers, as set forth.

2. In a box-assemblying machine, a cradle, means for holding parts of a box on the cradle, a frame for supporting the cradle, the said frame consisting of a horizontal part a, uprights c, c', integral with the part a, and provided at their tops with heads having bearings for transverse members on the cradle, the part a of frame being provided with a pedestal under part c', as set forth.

3. In a box-assemblying machine, an oscillating cradle provided with clamping-plates two pairs of said plates being connected with toggle-joints, said joints being in the axial line of the cradle when the plates are set in a closed position, as set forth.

4. In a box-assemblying machine, a movable cradle provided with means for holding parts of a box, the said cradle consisting of two triangular plates c' c' connected by rods d, and the said end plates being provided with transverse members, as set forth.

5. In a box-assemblying machine, a cradle having a horizontal bed for supporting a box, vertical end plates connected to the bed and having

transverse members which are mounted in a stationary frame, one of said transverse members having a screw-threaded socket in which is mounted a screw for adjusting one of the clamping-plates of the machine, as set forth.

6. In a box-assemblying machine, a cradle, the ends of which have transverse members mounted in the heads of a stationary frame, the said cradle being provided at its ends with projecting arms, one of which carries a counterweight and another a spring-mechanism which engages notches in a segment on one of the heads of the stationary frame, as set forth.

7. In a box-assemblying machine having plates for clamping the ends of the box, plates for clamping a middle partition in the box, and toggle devices for closing said plates, the said devices being connected together with means for throwing them out of their clamping position, as set forth.

8. In a box-assemblying machine, plates for clamping opposite parts of the box with toggle-levers connecting two of the plates so as to set both plates at once, as set forth.

9. In a box-assemblying machine, plates which clamp two opposite parts of a box, the said plates being connected by toggle levers or joints and one of said levers being provided with means for adjusting same, as set forth.

10. In a box-assemblying machine a stationary frame, provided with heads which have bearings for the transverse of a movable cradle, said bearings being provided with end-thrust cups or parts having friction-disks, as set forth.

11. In a box-assemblying machine, sliding brackets on which are mounted plates for clamping the box interiorly, and plates for clamping box exteriorly, one of said exterior plates being movable, and provided with means for disengaging the interior plates from parts of the box when the exterior plate is moved longitudinally.

12. A box-assemblying machine, comprising a stationary frame, a cradle provided with two end parts, having transverse members in the stationary frame, a clamping-plate attached to one of said end parts of cradle, a movable clamping-plate having a screw entering the other end part, a wheel for rotating said screw, intermediate clamping-plates having toggle connections, said plates being mounted on brackets which slide on rods of cradle, and connections for engaging the brackets and moving the intermediate plates after one of the end plates has been released from its clamping position, as set forth.

13. A machine of the class described, having an oscillating cradle, means for retaining cradle in a set position, and a longitudinal pivoted gage provided with means for bringing the gage into a position along the side of cradle, so that the parts of a box placed on the cradle may be aligned, as set forth.

698,483. BRAIN-VALVE FOR CYLINDERS. GEORGE FAITH and THOMAS ROSE, Indiana, Pa. Filed June 1, 1901. Serial No. 93,776. (No model.)

Claim.—1. The combination with a valve-barrel having springs at the opposite ends thereof, of ball-valves in position to strike the springs, and a rod interposed between and in the path of the balls for always causing the displacement of one of the balls from its seat.

2. The combination with a valve-barrel made in sections secured together the ends of the inner section forming valve-seat, and the outer section having longitudinal ribs in their bores and cushion devices at their outer ends, of ball-valves centered between the ribs, a rod independent of these valves and interposed between them and guides for holding the rod loosely centered in the direct longitudinal path of the valves.

3. The combination with a valve-barrel having two valve-seats, of two ball-valves entirely independent of each other, and a rod interposed loosely between the valves, the length of the rod being such that it must be struck with each coating of a ball-valve, and spiral springs located at the outer ends of the barrel.

698,484. NEEDLE-BAR-GUIDING MECHANISM FOR SEWING-MACHINES. WILLIAM FORTY, Baltimore, Md. Filed Nov. 8, 1901. Serial No. 91,800. (No model.)

Claim.—1. In a sewing-machine, the combination with the needle-bar; and the cross-head carried thereby, said cross-head carrying a direct

adjustable gill; of a plate having a race for said gill detachably carried by the face-plate, said race-plate having means preventing a movement of the gill laterally.

2. In a sewing-machine, the combination with the needle-bar; and the cross-head carried thereby, said cross-head carrying a slitted adjustable gill; of a plate having a race for said gill detachably carried by the face-plate, said plate having a slot of a length to permit of the full longitudinal movement of the gill, whereby lateral movement of the gill will be prevented.

3. In a sewing-machine, the combination with a plate having a gill-race adapted to prevent lateral movement of the gill; of a cross-head having a slitted gill movable longitudinally of the race said gill having means constructed to expand the sides thereof for taking up wear.

4. In a sewing-machine, the combination with a plate having a gill-race adapted to prevent lateral movement of the gill; of a reciprocating cross-head carrying a gill, said gill having a slit; and an adjusting-screw carried by said gill and adapted to expand the sides of said gill to take up wear.

5. In a sewing-machine, a needle-bar; a cross-head carried thereby; a gill carried by the cross-head, said gill being slitted longitudinally; an adjusting-screw carried by the gill and adapted to expand the sides of the gill; and a plate having a gill-race detachably carried by the face-plate, said race extending on opposite sides of the gill.

698,485. TWYER FOR FURNACES. WILLIAM R. FORTER, Union, N. Y. Filed July 26, 1899. Serial No. 24,912. (No model.)

Claim.—1. The combination in a furnace of a tryer-opening having a vertical extent equal at least to the thickness of the furnace-wall at the tryer-opening, a plate for said opening removable without necessitating the removal of other coating parts and having a blast-opening and means for conducting the air to said blast-opening, substantially as set forth.

2. The combination in a furnace of a tryer-opening and its surrounding casing, said opening and casing being not less in vertical extent than the distance from the inner face of the wall of the furnace, to the outer edge of the bottom wall of the casing, a removable plate having a blast-opening, means for conducting the air to said blast-opening and means for opening and closing the casing, substantially as set forth.

3. A furnace having a tryer-opening of a size to permit the introduction of a bar at an acute angle with the axis of the furnace, as set forth, a removable plate for said tryer-opening having a blast-opening therein and a casing surrounding said tryer-opening, substantially as set forth.

4. The combination with a furnace having the large tryer-opening 3 of a tryer-casing 4 surrounding the tryer-opening and having an extended upper wall and a lower or bottom wall shorter than the upper wall, and a door closing the outer end of said tryer-casing, a removable plate closing the tryer-opening and a blast-opening, through said plate, substantially as set forth.

5. The combination with a furnace having a large tryer-opening, of a tryer-plate removable without necessitating the removal of other coating parts, and having a blast-opening of smaller area than that of the tryer-opening, and means for conducting the air-blast to said blast-opening, substantially as set forth.

698,486. LOCK. ARON FRANKMANN, Copenhagen, Denmark. Filed Feb. 12, 1899. Serial No. 25,123. (No model.)

Claim.—1. In a safety-lock a reversible key-box 1 provided with spiral or labyrinthine guideways for a ball 2; a key which is provided with a hook-like bow 3, having guideways and a ball 2 corresponding to those of the key-box, and by engagement with a stop of the key-box turns said

box so as to make the ball 2 roll to the outer throat, and means for pushing the ball inside from said position, a ball released by said ball when pushed inside.

2. In a safety-lock comprising the reversible key-box with labyrinthine guideways, a ball 2 rolling therein, a key having hook-like bow and hook-like bow with the guideways, and a ball 2 rolling therein, and means whereby both balls may be brought to a central position by turning said key, the combination with said parts of a spring-pressed pin 7 playing in the hollow shank of said key and arranged to enter a small hole in the center of the key-box, whereby when said pin is pushed forward the ball 2 in said key-box is pushed back, a spring-ball released by such action, and a door-bolt forced out by said spring-ball when released.

3. In a safety-lock comprising the reversible key-box with labyrinthine guideways, a ball 2 rolling therein, a key having similar guideway, and a ball rolling therein, a spring-pressed ball, and a door-bolt acted upon by said spring-pressed ball when released, the combination with said parts of an angular lever 19 provided with a lock 20 engaging said spring-ball to hold it in a retracted position, and means for pushing the ball 2 in the key-box from a central position against said lever to disengage it and release the spring-ball.

4. In combination with the spring-ball 21 and the engaging latch-lever 19 a pin 20 fastened to said ball and playing in a slot in the catch-box, whereby said ball may be moved back to engagement with the latch-lever.

5. In combination with the spring-ball 21 and engaging latch-lever 19 a manually-operated disengaging-lever 27 pivotedly mounted upon the catch-box and acting at one end upon the hooked end of the latch-lever to disengage it from the spring-ball and release the latter.

6. The combination with the spring-pressed ball, the latch-lever by which it is held, the door-bolt, the ball 2 and its central pocket, of the catch 17, the forced spring 18 and rod or pin 7 movable in the shank of said key.

698,487. TYPE-WRITER. ARTHUR R. FINE, Peabody, N. Y. Filed Dec. 4, 1899. Serial No. 25,026. (No model.)

Claim.—The combination with the frame and platen of a typewriter of brackets 4 attached to the frame of the machine and supporting a track 4, a paper-roll carrier 5 with arms removably hooked upon the platen-carrying rod 7 embracing the platen-frame between them as described, the outer central end of said frame having a roller 6 that rides upon the track 4, the paper-roll, supported upon the carrier 5 by journals 6 as shown, and a spring 15 resting upon one of said journals and having a strong initial pressure regulable by means of a screw 16, substantially as herein set forth.

698,488. TELEGRAPH CASE. CHARLES L. GILBERT, Cleveland, Ohio. Filed Feb. 4, 1899. Serial No. 24,897. (No model.)

Claim.—1. A telescopic case comprising a frame-like section 4 having a fixed central partition 5, an upper section 1 adapted to receive said section 4 and a lower section 7 adapted to be inserted and inserted within the section 4 beneath the partition thereof and stops for seating said section, substantially as specified.

2. In a telescopic case, the combination with a frame-like section 4 having its upper and lower sides open, a fixed horizontal partition 5

said section and suitable strengthening-strips on the under side of said partition, of an upper section 1 adapted to receive said section 4, a lower box-like section 7 adapted to be inserted within the lower portion of the section 4 and means for seating said sections, substantially as specified.

698,489. SHAFT-SUPPORT FOR VEHICLES. JAMES H. GARDNER, Morris Plains, N. J. Filed May 31, 1901. Serial No. 68,561. (No model.)

Claim.—1. A shaft-support comprising a beam, links pivoted to opposite sides of the beam and adjustable thereon, an upright pivoted to the opposite ends of the links and between them at a point above the lower end of the upright to permit the upright to stand with its lower end upon the beam, and a stop connecting the links above the beam and in the path of rearward movement of the lower end of the upright to limit the forward movement of the upper end of the upright.

2. A shaft-support comprising a beam having a plurality of transverse perforations, links disposed against the sides of the beam and having a pivot-bolt engaged with the perforation and adapted for engagement with the whole number of perforations interchangeably, an upright pivoted between the upper ends of the links at a point above its lower end, said upright being adapted to stand with its lower end upon the beam and a bolt engaged with the links in the path of rearward pivotal movement of the lower end of the upright to form a stop therefor and prevent forward movement of the upper end of the upright.

698,490. TUBULAR BRAKE. JAMES A. GARDNER, New York, N. Y., assignor to Knott's Manufacturing Company, New York, N. Y., a Corporation of New York. Filed Nov. 20, 1901. Serial No. 64,099. (No model.)

Claim.—1. As a new and useful article of manufacture a tubular brake consisting of a braided body, having water or air of a general undulating form running longitudinally thereof and valve edges united by a thread or filament after the manner of a loop-knot.

2. As a new and useful article of manufacture, a tubular brake having valve edges of a general undulating form bound together by a thread substantially as set forth and ribs or vanes of a general undulating form running longitudinally thereof.

3. As a new and useful article of manufacture, a tubular brake consisting of a braided body, having two valve edges of wavy form, the waves of one edge fitting the waves of the other edge, and means for seating said edges substantially as described.

4. As a new and useful article of manufacture, a tubular brake having extending longitudinally thereof wavy edges, the waves of one edge fitting the depressions between the waves of the other edge, and a binder thread entering both edges and binding the said edges together.

698,491. STATION-ANNUNCIATOR FOR RAILWAY-CARS. GEORGE HALL, Peabody, Ohio. Filed Jan. 20, 1902. Serial No. 31,734. (No model.)

Claim.—1. In a station-annunciator for railway-cars, a conductor's indicator having an indicator member for each stopping-point, an operator's annunciator having an annunciating device for each stopping-point, connections between each indicator member and the corresponding annunciating device, means capable of operation from any place in the car for indicating any desired indicator member, and means for actuating the corresponding annunciating device.

2. In a station-annunciator for railway-cars, a conductor's indicator, an operator's annunciator adapted and arranged to annunciate the point designated on the indicator, a pointer on the indicator, and a rod connected with said pointer and disposed within reach, lengthwise of the car, whereby the indicator may be operated from any place within the car.

3. In a station-annunciator for railway-cars, an indicator, a rod which extends through the car and which is adapted and arranged to operate the indicator, an annunciator connected with said indicator, and means, capable of being operated from any part of the car, for causing the annunciator to register the point marked on the indicator.

4. A station-annunciator for railway-cars comprising a conductor's indicator having indicator members corresponding with the stations, an operator's annunciator having electrically-controlled annunciating devices corresponding with said indicator members, open electric connections between each of said indicator members and its corresponding annunciating device, a movable member adapted to designate either of said indicator members and to thereby throw either of said indicator members into electrical connection with its corresponding annunciating device, means for actuating said movable member from any place in the car, a make-and-break device in said electrical connections, and means for actuating said make-and-break device from any place in the car.

698,492. CLAMPING DEVICE FOR FRUIT-JAR LIDS. WALTER V. HARR, Detroit, Mich. Filed Apr. 4, 1901. Serial No. 65,090. (No model.)

Claim.—1. The combination with a pair of levers having inwardly-extending cam, of a body portion pivoted in said cam and having diverging arms terminating in upward cam, and a clamping-rod connected at each end to the ends of the said levers and passed twice through said upward cam and forming a circular loop doubled outside said cam, all substantially as shown and described.

2. The combination with a pair of levers having inwardly-extending

ing arms and end portions 11 with apertures 12, of a body portion pivoted in said cars and having diverging arms terminating in upturned ears substantially in line with said apertures, and a clamping-wire connected at each end to said levers at the ends thereof in said apertures and passed twice through the upturned ears of said arms in different planes and forming a circular loop doubled outside said arms with the portion between said ears of the arms and the ends of the body portion inclined, all substantially as shown and described.

698,498. VEHICLE. ARTHUR HERRMANN, New York, N. Y. Filed Oct. 18, 1901. Serial No. 79,100. (No model.)

Claim.—1. In a vehicle, the combination of the body and an axle, with vertical upright guides connected with the body on each side thereof and through which the axle projects, and springs attached to the body at points in front and rear of the guides and passing through said guides and resting freely on the top of the axle therein, substantially as described.

2. In a vehicle, the combination with the body and an axle, of vertical guides secured to the body and having passages through them in two planes at right angles to each other, the axle passing through and guided by the openings in one plane and springs passing through and guided by the openings in the other plane.

3. In a vehicle, the combination with the body and an axle, of vertical guides secured to the body, each consisting of four uprights placed at the corners of a rectangle and forming a box-like structure through which the axle projects and in which it is guided, the axle being provided with curved surfaces bearing against the inner sides of the outer uprights, respectively.

4. In a vehicle, the combination with the body, and vertical guides carried thereby and consisting of four braces forming an open box-like structure, of semi-elliptical springs passing through the open sides of said guides and having attached thereto a shank engaging with the guides to support and guide the springs, substantially as described.

5. In a vehicle, the combination of a body, an axle mounted later to assume an inclined position with respect to the floor of the body, a spring interposed between the body and the axle and resting freely upon the latter and a curved shoe interposed between the spring and the axle affording a rolling motion when the axle assumes an inclined position with respect to the floor of the body and means for maintaining the spring in its working position.

6. In a vehicle, the combination of a body, an axle mounted free to assume an inclined position with respect to the floor of the body, an elliptical or semi-elliptical spring interposed between the body and the axle, resting freely upon the latter and occupying a plane at right angles to the axle and a curved shoe interposed between the spring and axle, affording a rolling motion when the axle assumes an inclined position with respect to the floor of the body.

698,494. BRAKING DEVICE FOR COMPENSATING GEARS. ARTHUR HERRMANN, New York, N. Y. Filed Nov. 12, 1901. Serial No. 82,857. (No model.)

Claim.—1. In a self-propelled vehicle, the combination of a divided shaft, a compensating-gear drum applied thereto, an idler or supplemental wheel loosely mounted on one part of said divided shaft and normally

rotating at substantially the same speed as said drum, and means operated by the development of substantial difference in speed of rotation between said idler and said drum for causing the stoppage of the compensating-gear device carried by said drum, substantially as and for the purposes described.

2. The combination of a divided shaft, a compensating gear applied thereto, an idler carried by one part of said divided shaft, a braking device capable of application to one or more of the elements of said gear, and means for applying said braking device, said means being actuated by the development of substantial difference in the speed of rotation between said compensating gear and said idler, substantially as and for the purposes described.

3. In a compensating or differential gear, the combination of a series of gears in planetary relation to each other, a driving-drum in operative relation thereto, a divided shaft upon which said gears are mounted, an idler loosely mounted upon one part of said divided shaft, a rocking spindle carried by said driving-drum, braking devices applied to one or more of the elements of said compensating gear, a rack mounted on said rocking shaft, a pinion carried by the axle of said hub and arranged to intermesh with said rack, and means for developing at will a difference in speed of rotation between said idler and said drum, substantially as and for the purposes described.

4. A braking device for compensating gears of self-propelled vehicles comprising a divided shaft an idler loosely mounted upon one part of said shaft, a pinion carried at the axle of rotation of said idler, a compensating-gear drum, a rocking spindle carried thereby, a segmental rack meshing with said pinion and carried by said spindle, and a brake in operative relation to one or more of the elements of the compensating gear and arranged to be applied by the movement of said rocking shaft, substantially as and for the purposes described.

698,495. FURNACE FOR HEATING OR CHILLING METALS. HERBERT H. HEWITT, Buffalo, N. Y. Filed Oct. 18, 1901. Serial No. 79,904. (No model.)

Claim.—1. A furnace of the character described having a combustion-chamber the wall whereof is perforated to admit the fuel-supply and a vertically-adjustable cover or diaphragm extending over and serving to define the effective volume of said combustion-chamber.

2. A furnace of the character described having a combustion-chamber the wall whereof is perforated to admit the fuel-supply and a vertically-adjustable cover or diaphragm extending over and serving to define the effective volume of the combustion-chamber, said cover or diaphragm being provided with an opening of small diameter for the escape of products of combustion.

3. A furnace of the character described having a combustion-chamber perforated to admit the fuel-supply and a vertically-adjustable cover or diaphragm extending over and serving to define the effective volume of the combustion-chamber, the diameter of said cover or diaphragm being sufficiently smaller than the interior diameter of the body of the combustion-chamber to permit said cover or diaphragm to be adjusted to any desired point within the combustion-chamber.

4. A furnace of the character described having a combustion-chamber perforated to admit the fuel-supply and a vertically-adjustable cover or diaphragm extending over and serving to define the effective volume of the combustion-chamber, said cover or diaphragm being of somewhat smaller diameter than the interior diameter of the combustion-chamber whereby the cover or diaphragm can be adjusted to any desired point within the combustion-chamber and means for raising and lowering said cover or diaphragm.

698,496. ASH OR REFUSE CAN. THOMAS HILL, Jersey City, N. J. Filed Jan. 20, 1901. Serial No. 64,900. (No model.)

Claim.—1. The tapered ash or refuse can of the character adapted for "nesting," having and carrying below its bottom the series of springs forming a spring base-support, said springs being set within the vertical plane of the lower edge of the can so as not to interfere with the "nesting" and being adapted when the cans are nested to contact with the bottom of the next lower can to prevent the can from unduly entering the next lower can and to aid in the separation of the cans, substantially as shown and described.

2. An ash or refuse can having the bottom construction comprising the disk 12 and frame 13 secured together and to the body of the can, said frame 13 having the depressed portion 15 provided with openings 16, combined with the springs 17 fastened at their outer portions, and having their inner free ends projected through the said openings 16; substantially as set forth.

3. The tapered ash or refuse can of the character adapted for "nesting," having at its upper edge the riveted band 18, at the opposite sides of its upper edge adjacent to said band the handles 19, and at convenient intervals along said upper edge the springs 20 to prevent the nested cans from unduly sticking together or rattling, said springs being directly secured to and carried by the can, substantially as shown and described.

4. The ash or refuse can of the character adapted for "nesting," having the springs below and carried by its lower end and affording a yielding support or base for the can, and also having at intervals along its upper edge the springs 20 secured directly to and carried by the can and adapted to prevent the nested cans from sticking together or rattling, said bottom springs, when the cans are nested, being adapted to contact with the bottom of the next lower can to prevent the can from unduly entering the said lower can and to aid in the separation of the cans, substantially as and for the purposes set forth.

698,497. ASH OR REFUSE CAN. THOMAS HILL, Jersey City, N. J. Filed Jan. 20, 1901. Serial No. 64,901. (No model.)

Claim.—1. The ash or refuse can having and carrying below its bottom the series of radial leaf-springs 16 secured fastened at their inner portions to the central portion of the bottom of the can so as to be carried thereby, combined with the series of guides 17 also secured to the bottom of the can, said springs from their inner portions extending downward and outward and then upward and inward through said guides, substantially as shown and for the purposes set forth.

2. An ash or refuse can having the bottom 11 provided with the similar flange 12 by which said bottom may be secured to the can-body, combined with the disk 15 secured to the center of the said bottom, the guides 17 also secured to said bottom, and the springs 18 secured at one end to said disk 15 and at the other end being freely movable within said guides 17, said springs 18 affording a support for the can; substantially as set forth.

3. The ash or refuse can having upon its sides the series of metal springs 10 rigidly secured at one end, combined with the guides 20 also secured to the sides of the can and adapted to receive the other end of said springs; substantially as shown and set forth.

698,498. WRENCH. HARRY DE P. WILLIAMS, Lancaster, N. H., assignor of one-half to Moses A. Hastings, Lancaster, N. H. Filed Feb. 3, 1902. Serial No. 62,804. (No model.)

Claim.—1. A wrench including a fixed and movable jaw between which the article is received, said movable jaw slidable upon the shank of the fixed jaw and having members extending on each side of and parallel with the shank and substantially embracing the fixed jaw.

2. A wrench including a bar and fixed and movable jaws said movable jaw being slidable upon the shank of the fixed jaw and pivotally mounted at its lower portion and having members extending from its upper portion one on each side of the fixed jaw.

3. A wrench including a bar having a fixed jaw, a jaw slidable on the bar, a collar or yoke also slidable on said bar and collar or yoke and slidable jaw being pivotally united at a point in front of the bar, and said movable jaw having a projecting portion extending in the direction of the length of the shank of the fixed jaw and adapted to be engaged by the pipe or rod to rock the movable jaw about its pivot, and a screw parallel with the bar and in the plane of the pivot of the movable jaw, whereby said movable jaw is adjusted toward and from the fixed jaw.

4. A wrench including a bar having a fixed jaw, a jaw slidable on said bar and a collar or yoke also slidable on the bar and pivotally connected with the slidable jaw said slidable jaw having portions extending in the direction of the length of the shank and adapted to be engaged by the pipe or rod to rock the movable jaw about its pivot, and a screw carried by the pivoted jaw and adapted to engage said bar to limit the rocking movement of the jaw.

5. A pipe-wrench consisting of a bar having a handle portion and a fixed jaw, a yoke slidable on the bar and a jaw also slidable on the bar and pivotally connected with said yoke forward of the plane of the front of the bar, an operating-screw parallel with the bar and in the plane of the pivotal axis of the movable jaw, and pins or fingers extending from the movable jaw substantially parallel with the bar and embracing the outside of the latter.

698,499. MANIPULATOR OF FIGURES IN TYPE. FARMER, BENJ. A. WILSON, Allentown, Pa. Filed Mar. 21, 1901. Serial No. 62,805. (No specimens.)

Claim.—1. The method of producing figured lettering, which consists in withholding from action certain predetermined pieces, bearing loops of a thread of one kind, during the lettering of successive columns with thread of another kind, and upon the completion of a predetermined number of these columns, again drawing the inactive needles into operation, whereby the loops which they all carry from the first column are

projected forward into the territory of the succeeding course, substantially as described.

2. The method of producing figured knitting, which consists in withholding from action certain predetermined needles, bearing knitting-loops, during the knitting of a predetermined number of successive courses, and then knitting a course with a thread of a different kind during which the formerly inactive needles are again thrown into action, whereby the loops formed on these needles from the latter thread are drawn back into the territory of the preceding course, substantially as described.

3. The method of producing figured knitting, which consists in withholding from action certain predetermined needles, bearing loops of thread of one kind, during the knitting of successive courses with thread of another kind, and upon the completion of a predetermined number of these courses, again throwing the inactive needles into operation, during the knitting of a succeeding course with the thread of the first kind, whereby the effect of a link or chain figure is produced, substantially as described.

4. The herein-described figured knit fabric, which contains courses of threads of different kinds, having certain of the loops of a course formed of one kind of thread drawn forward over one or more intervening courses of a different kind of thread, and knit into a subsequent course; substantially as described.

5. The herein-described figured knit fabric, which contains courses of threads of different kinds, having certain of the loops of a course drawn forward over one or more intervening courses, and knit into a subsequent course formed of a thread of a different kind from the intervening course or courses; substantially as described.

6. The herein-described figured knit fabric, which contains courses of threads of different kinds, having certain of the loops of a course formed of one kind of thread drawn forward over one or more intervening courses of a different kind of thread and knit into a subsequent course formed of the same kind of thread as the course from which the loops were drawn forward; substantially as described.

7. The herein-described figured knit fabric, which contains courses of threads of different colors, having certain of the loops of a course of a thread of one color drawn over the face of one or more intervening courses of threads of a different color, and knit into a subsequent course; substantially as described.

8. The herein-described knit fabric, which contains courses of threads of different kinds, having certain of the loops of a course of one kind of thread drawn forward over one or more intervening courses of a different kind of thread, and knit into a subsequent course, of which the corresponding loops are drawn backward over one or more of the intervening courses of a different kind of thread and knit into a subsequent course with the forwardly-projecting loops; substantially as described.

9. The herein-described figured knit fabric, which contains courses of threads of different colors, having certain of the loops of a course formed of one colored thread drawn forward over one or more intervening courses

of a different-colored thread, and knit into a subsequent course, and also having certain loops formed of one colored thread drawn backward over one or more intervening courses of a different-colored thread, and knit into a preceding course; substantially as described.

10. A continuously-knit tubular web, containing courses knit with threads of different colors, and having certain of the loops formed of one color drawn forward over the face of intervening courses of a different color, and interlooped into a subsequent course; substantially as described.

11. A continuously-knit seamless stocking, the tubular portion of which contains courses knit with threads of different colors and having certain of the loops formed of one color drawn forward over the face of intervening courses of a different color, and interlooped into a subsequent course; substantially as described.

698,500. OVER. FRANK F. HOFFMAN, Arlington, N. H. Filed Feb. 11, 1908. Serial No. 92,304. (No model.)

Claim.—A device of the class described comprising a base-plate having diagonal strengthening-ribs and uprights secured upon the ribs at the ends thereof, the upper portions of the uprights at opposite sides of the base-plate being laterally offset in opposite directions at points intermediate of their ends to form supporting-shoulders and guides thereabove.

698,501. SAW-SPINDLING-MACHINE. FRANK HOFFMAN, Milford, Pa. Filed Nov. 11, 1901. Serial No. 51,008. (No model.)

Claim.—1. In a saw-spindling-machine the combination of two main-drums, one of which is adjustable, and mechanism for driving them, the blades at one side of each of said drums, flanged feed-rolls at each side of the machine, a case inclosing said drums and flange, and a spout connected with said case, for carrying off the dust therefrom, substantially as set forth.

2. In a saw-spindling-machine, the combination of two main-drums one of which is mounted on adjustable bearings, the blades at one side of each of said drums, and flanged feed-rolls at each side of the machine, one of which rolls is provided with a yielding bearing, and mechanism for driving said feed-rolls in unison substantially as set forth for the purpose set forth.

3. In a saw-spindling-machine, the combination of main-drums B F, adjustable bearings G for the drum B, flange F and pulleys on the shaft of each drum, driving-pulleys g g' on a cross-shaft H and belt A H, flanged feed-rolls H H' at each side of the machine, shafts and mechanism for driving said feed-rolls, adjustable and yielding bearings j' for the upper of said feed-rolls, a case Q inclosing the main-drums and flange mechanism, and a spout P leading therefrom, substantially as set forth for the purpose set forth.

698,502. CARBON-PILE HEATER. LOW E. BROWN, Chatham, Ohio. Filed May 9, 1901. Serial No. 92,003. (No model.)

Claim.—1. An article of manufacture consisting of a box-shaped structure of metal having

ing a rear wall and a wall in front thereof and constituting an air-chamber open at the bottom, and the forward of said walls terminated below by an open-top trough extended from side to side and partly blanketing the lower portion of the inclosed chamber, said forward wall having perforations through it whereby the air heated in the chamber between the two walls is discharged forwardly to mingle with the flame that passes along the front of the forward wall, and said structure having other perforations to discharge air rearwardly across the front edge of the trough.

2. An "open-fire" burner for burning between, consisting substantially of two or more open-top feed-troughs disposed one above and behind the other, in combination with side, rear and front walls including an air-chamber open below the troughs and extended upwardly at rear, perforated to discharge air rearwardly across the front edge of each trough and forwardly through the front wall of the vertical rear extension, the sides of the inclosure being extended forward as a curb extending from the outer edge of the lowest trough to or near the top of the vertical rear extension of the air-chamber, substantially as set forth.

698,503. PRESSURE-ENGINE. FREDERICK H. BULL, Brooklyn, N. Y. Filed May 8, 1907. Serial No. 82,323. (No model.)

Claim.—1. In a pressure-engine, the combination with the cylinder, piston, crank-shaft, and connections between the piston and the crank-shaft, of valves for controlling the admission of the operating fluid to and from the cylinder, a pair of oppositely-arranged cams on the crank-shaft, and means for operatively connecting the valves with one of said cams and for simultaneously disconnecting them from the other of said cams, whereby the valves may be operatively connected with either of said cams, substantially as set forth.

2. In a pressure-engine, the combination with the cylinder, piston, crank-shaft, and connections between the piston and crank-shaft, of valves for controlling the admission of the operating fluid to and from the cylinder, a pair of oppositely-arranged cams on the crank-shaft, a pair of valve-operating bars engaging said cams, and means for bringing either of said bars into operative relation with the valves, substantially as set forth.

3. In a pressure-engine, the combination with the cylinder, piston, crank-shaft, and connections between the piston and crank-shaft, of valves for controlling the admission of the operating fluid to and from the cylinder, a pair of oppositely-arranged cams on the crank-shaft, a pair of valve-operating bars engaging said cams, and a pivoted arm connected to said bars for bringing either of them into operative relation with the valves, substantially as set forth.

4. In a pressure engine, the combination with the cylinder, piston, crank-shaft, and connections between said crank-shaft and piston, of a valve-chamber connected to the cylinder, valves in said chamber controlling the admission and exit of the pressure fluid to and from the cylinder, a pair of operating-cams on the crank-shaft, a pair of valve-operating bars having oppositely-disposed wide and narrow portions, and a valve-rod connected to the valves and co-operating with the said bars, substantially as set forth.

5. In a pressure-engine, the combination with the cylinder, piston, crank-shaft, and connections between said crank-shaft and piston, of a valve-chamber connected to the cylinder, valves in said chamber controlling the admission and exit of the pressure fluid to and from the cylinder, a pair of operating-cams on the crank-shaft, a pair of valve-operating bars having oppositely-disposed wide and narrow portions, and a valve-rod connected to the valves and co-operating with the said bars, the valve-operating bars having inclined sections connecting the wide and narrow portions thereof and with which inclined sections the valve-rod co-operates to stop the engine, substantially as set forth.

6. In a pressure-engine, the combination with the cylinder, piston, crank-shaft, and connections between said crank-shaft and piston, of a valve-chamber connected to the cylinder, valves in said chamber controlling the admission and exit of the pressure fluid to and from the cylinder, a pair of operating-cams on the crank-shaft, a pair of valve-operating bars having oppositely-disposed wide and narrow portions, a valve-rod connected to the valves and co-operating with the said bars, and a pivoted arm connected to said bars, substantially as set forth.

7. In a pressure-engine, the combination with the high and low pressure cylinders, the pistons thereof, the crank-shaft, and connections between said pistons and the crank-shaft, of a valve-chamber, an admission-valve for the high-pressure cylinder, exhaust-valves for both cylinders, a valve-rod operating said valves, a pair of cams on the crank-shaft, and means for operating said valves from either of said cams, according to the direction in which the crank-shaft is to be rotated, substantially as set forth.

8. In a pressure-engine, the combination with the high and low pressure cylinders, the pistons thereof, the crank-shaft, and connections between said pistons and the crank-shaft, of a valve-chamber, an admission-valve for the high-pressure cylinder, exhaust-valves for both cylinders, a valve-rod operating said valves, a pair of cams on the crank-shaft, and a pair of valve-operating bars co-operating with said cams and connected to said valves, substantially as set forth.

9. In a pressure-engine, the combination with the high and low pressure cylinders, the pistons thereof, the crank-shaft, and connections between said pistons and the crank-shaft, of a valve-chamber, an admission-valve for the high-pressure cylinder, exhaust-valves for both cylinders, a valve-rod operating said valves, a pair of cams on the crank-shaft, a pair of valve-operating bars co-operating with said cams and connected to said valves, and a pivoted arm connected to said bars for operating the latter, substantially as set forth.

10. In a pressure-engine, the combination with the high and low pressure cylinders, the pistons thereof, the crank-shaft, and connections between said pistons and the crank-shaft, of a valve-chamber, an admission-valve for the high-pressure cylinder, exhaust-valves for both cylinders, a valve-rod operating said valves, a pair of cams on the crank-shaft, and a pair of valve-operating bars co-operating with said cams and connected to said valves, said bars having wide and narrow portions and inclined sections connecting said portions, substantially as set forth.

11. In a pressure-engine, the combination with the high and low pressure cylinders, the pistons thereof, the crank-shaft, and connections between said pistons and crank-shaft, of a valve-chamber, a valve-rod reciprocating in said chamber, means for operating said valve-rod, an exhaust-valve for the low-pressure cylinder rigidly carried by the valve-rod, an exhaust-valve for the high-pressure cylinder longitudinally movable on the valve-rod, and a steam-admission valve for the high-pressure cylinder actuated by said valve-rod near the completion of the movement of the latter, substantially as set forth.

698,504. VALVE. CHARLES W. HUNT, West New Brighton, N. Y. Filed Oct. 31, 1901. Serial No. 92,009. (No model.)

Claim.—1. A valve comprising members separated longitudinally for relative movement, means to secure said members together for common movement, and rings placed about said members to receive the outward pressure thereof, substantially as shown and described.

2. A valve comprising a shaft, valve members supported by said shaft for movement toward and from each other in the plane of the axis, and rings placed about said valve members to receive the outward pressure, substantially as shown and described.

3. A valve comprising a shaft, arms on said shaft, rods or pins carried by said arms and valve members mounted upon said rods or pins for movement toward or from each other, substantially as shown and described.

4. The combination of a steam-cylinder, valve-chest and confining valve, cylinder-ports being formed in the valve-chest and asymmetrically disposed, one being near the cylinder and the other remote therefrom, an inlet-rod being formed in the valve-chest near the cylinder and exhaust-ports being formed in the steam-chest respectively near the cylinder-ports, whereby one of said exhaust-ports is near the lowest point of the steam-chest, substantially as shown and described.

698,505. GUARD FOR PIANOS. ALBERT A. HENRY, Chicago, Ill. Filed May 22, 1901. Serial No. 61,546. (No model.)

Claim.—1. A guard for pianos consisting of a frame adapted to enclose the piano substantially at the level of the keyboard, and means for removably supporting said frame in such position upon the piano.

2. A guard for pianos consisting of a frame adapted to enclose the piano substantially at the level of the keyboard and end shields for the ends of the piano, held in place by said frame.

3. A guard for pianos consisting of front and back pieces, and pieces detachably secured to said front and back pieces, locking devices for securing said members together, and means carried by said back piece for supporting the same upon the piano, substantially as described.

4. A guard for pianos consisting of front and back pieces, and pieces detachably secured to said front and back pieces, locking devices for securing said members together, and inwardly-projecting forks carried by said back piece for supporting the same upon the piano, substantially as described.

5. A guard for pianos consisting of a frame adapted to enclose the piano substantially at the level of the keyboard and consisting of a plurality of removably-connected parts.

6. A guard for pianos consisting of a frame adapted to enclose the piano substantially at the level of the keyboard and end shields for said piano removably held in place by said frame.

7. A guard for pianos consisting of a frame adapted to surround the piano substantially at the level of the keyboard and check-shields carried by said frame adapted to cover the check-pieces of the piano.

8. A guard for pianos consisting of a frame adapted to surround the piano substantially at the level of the keyboard, and shields for the ends of said piano and check-shields for the check-pieces of said piano, all of the shields being supported by said frame.

9. A guard for pianos consisting of a plurality of detachably-connected members adapted to surround a piano and check-shields supported by certain of said members and removable with said members from the piano.

10. A guard for pianos consisting of a frame adapted to surround

the piano substantially at the level of the keyboard and consisting of front and back pieces and end pieces detachably connected respectively to said front and back pieces and end and check shields carried by said end pieces.

698,506. MECHANISM FOR FEMMING WOOL OR THE LIKE INTO RAGS. ALFRED E. ILLINGWORTH, Addingham, England. Filed Jan. 15, 1902. Serial No. 59,590. (No model.)

Claim.—A receptacle A provided with longitudinal spaced bars B and a press-head F with means of operating same, combined with a movable rigid and J, chains K, with means for securing same, and rods Q passed through the chain-links, substantially as described.

698,507. GAS-SAVING APPLIANCE. SYRIGER J. JENK, Pittsburgh, Pa. Filed Dec. 26, 1901. Serial No. 57,312. (No model.)

Claim.—1. In a gas-burning device, a top plate having a curved opening and a flange thereon having air-inlets at the edge thereof opposite the top plate and waste-product outlets between the air-inlets and the top plate.

2. In a gas-burning device, a top plate having an opening with a broken margin, and a flange on said plate said flange having a reduced portion adapted to enter a stove-top opening and a shoulder, forming a step for the device.

698,508. CARPET-CLEANING RACK. FRANK V. JOHNSON, New-Hag, Ill. Filed May 22, 1901. Serial No. 61,319. (No model.)

Claim.—1. In a carpet-cleaning rack, the combination of the frame 1, and means of support therefor; cross-pieces 6, pivotally secured by means of supporting-arms 4 to the frame 1; side 8; cross-pieces 14, and the cords 9 and 15 pivotally secured by means of supporting-arms 11 to the frame 1; cords 15; and means for securing the cross-pieces 6 and 14 in any desired position; substantially as shown and set forth.

2. In a carpet-cleaning rack, the combination of the frame 1, provided with loops 10; arms 4, pivotally secured to the frame 1, and provided with the ratchet-bars 9; cross-pieces 6; and cords 8; and means of support for the frame 1; substantially as set forth.

3. In a carpet-cleaning rack, the combination of the frame 1; legs 2, pivotally secured thereto; arms 4, pivotally secured to the frame 1; cross-pieces 6, detachably secured to the arms 4; and arms 11, detachably secured to the frame 1, and supporting the cross-pieces 14; cords 8; and cords 15; substantially as shown and described.

698,509. PRESS-SCALE. LEONARD T. JOHNSON, Brooklyn, N. Y. Filed Apr. 9, 1901. Serial No. 58,000. (No model.)

Claim.—1. In a weighing-scale, the combination with a sliding poise, of a rotary cylinder carrying computations, flexible connections between the poise and opposite ends of the cylinder, said connections being reversely wound about the cylinder and retaining means at the ends of the cylinder for preventing the slipping of the flexible connections therefrom, substantially as described.

2. In a weighing-scale, the combination with the beam, of forwardly-extending arms carried by the ends thereof having caps formed on their outer ends and provided with inclined ends and upwardly-extending legs, a casing mounted at its ends in said caps and formed with a longitudinally-extending right-opening in its upper portion, a cylinder mounted to revolve in said casing and carrying computations, a graduated bar secured to said scale, a track comprising two spaced rails secured to the upwardly-extending legs, a poise slidable on said track and provided with a pointer adapted to coact with the graduations of the bar, pulleys mounted between said rails at the ends of the track, a pulley mounted on one of said arms, and flexible connections between the poise and ends of the cylinder, said connections passing over the pulleys and wound about the cylinder reversely to each other, substantially as described.

3. In a weighing-scale, the combination with a sliding poise, of a rotary member carrying computations, a flexible connection between the poise and the member at points on opposite sides of the center of the latter, means for adjusting the length of the flexible connection between the poise and the respective points of attachment of said connection with the rotary member, and means whereby the same relative length of said connection between the poise and the points of attachment of said flexible connection with the rotary member may be preserved, substantially as described.

4. In a weighing-scale, the combination with a sliding poise, of a rotary member carrying computations, a flexible connection between the poise and points on opposite sides of the center of the rotary member, and means for adjusting said poise relatively to said flexible connection, substantially as described.

5. In a weighing-scale, the combination with a sliding poise, of a rotary member carrying computations, an adjustable member carried by the poise, and a flexible connection between said adjustable member and points on opposite sides of the center of the rotary member, substantially as described.

6. In a weighing-scale, the combination with a sliding poise, of a rotary member carrying computations, a block having a dot-and-curve connection with the poise, and a flexible connection between said block and points on opposite sides of the center of the rotary member, substantially as described.

7. In a weighing-scale, the combination with a sliding poise, of a rotary member carrying computations, a block to which the poise is adjustably attached, a flexible connection between said block and points on opposite sides of the center of the rotary member, and means carried by the block for adjusting the cords, substantially as described.

8. In a weighing-scale, two parallel-disposed spaced rails, a poise slidable on said rails and bifurcated to straddle the same, a rotary mem-

ber carrying computations, a block carried by the poise and disposed between the rails, flexible connections between said block and points on opposite sides of the center of the rotary member, and adjusting means carried by said block for effecting the adjustment of said flexible connections, substantially as described.

698,510. STEAM-ENGINE. WILLIAM A. JOHNSON, Emma, W. Va. Filed Aug. 13, 1901. Serial No. 71,964. (No model.)

Claim.—A steam-engine comprising a base having a cut-away portion at one end, a block secured in the cut-away portion and having parallel passages therethrough forming cylinders, a plate secured to the front end of the block, a plate secured to the rear end of the block, said plates covering both ends of both passages, a bearing-plate set into the base, vertically-spaced bearing-pieces spaced outwardly from each side of the first-named plate, cross-heads slidably engaged with the bearing-pieces, a crank-shaft mounted upon the base, connections between the cranks of the shaft and the cross-heads, pistons in the cylinders connected with the cross-heads, a steam-chest for the cylinders, separate cut-off mechanisms for the cylinders, and separate connections between the valve mechanisms and the crank-shaft for operating the valve mechanisms.

698,511. STRINGER. FREDERICK E. JOHN, Wakefield, Mass. Filed Sept. 4, 1901. Serial No. 74,394. (No model.)

Claim.—In a syringe, the combination with a bulb, of a cup seated in the mouth thereof having an outlet-opening in the bottom provided with a nozzle, an unobstructed passage between said nozzle and bulb, and one or more inlet-openings in the bottom of said cup also opening into said bulb, by which the liquid discharged from the nozzle is returned to said bulb, and a check-valve for each inlet-opening adapted in its automatic operation by the contraction and expansion of the bulb, substantially as described.

698,512. GOLF-BALL. BRADSHAW KIRKPATRICK, Boston, Mass., assignor to the Kongsbak Manufacturing Company, a Corporation of New Jersey. Filed Mar. 13, 1902. Serial No. 54,976. (No model.)

Claim.—1. A playing-ball comprising a casing consisting of a pair of overlapping sections, each section consisting of fabric and colloidal.

2. A playing-ball comprising a casing consisting wholly of a single layer of celluloid and lined with fabric, and a yielding sphere upon which said casing is cemented.

3. A playing-ball comprising a yielding filling and hemispherical cover-segments consisting wholly of plastic material and lined with fabric cemented upon said filling.

4. A playing-ball comprising welded hemispheres of gutta-percha upon which are cemented and compressed telescoping hemispheres of fabric and celluloid.

5. A playing-ball comprising a core, and hemispheres of gutta-percha welded thereon, and telescoping hemispheres composed of fabric and celluloid cemented and compressed upon said gutta-percha.

6. A playing-ball comprising a sphere of soft rubber; hemispheres of gutta-percha welded or joined upon said sphere; and telescoping hemispheres of fabric and celluloid cemented and compressed upon said gutta-percha.

7. A playing-ball comprising a sphere of gutta-percha; a spherical soft-rubber envelope thereon; an outer sphere of gutta-percha upon said envelope; and a telescoping covering composed of celluloid and fabric and cemented and compressed upon said outer sphere.

8. A playing-ball comprising a sphere of gutta-percha; a spherical soft-rubber envelope thereon; hemispheres of gutta-percha welded or joined upon said envelope; and a cover consisting of telescoping hemispheres of compressed fabric and celluloid cemented and compressed upon said gutta-percha.

9. A playing-ball comprising a sphere of gutta-percha; a spherical soft-rubber envelope thereon; hemispheres of gutta-percha welded or joined upon said sphere; and a covering consisting of telescoping hemispheres composed of fabric and celluloid secured upon said gutta-percha; said gutta-percha and celluloid holding said core under compression.

10. A playing-ball comprising a thin celluloid and fabric cover made in telescoping segments.

11. A playing-ball comprising a thin celluloid and fabric cover made in telescoping hemispherical segments which are compressed upon the ball.

12. A playing-ball comprising a sphere of soft rubber, and a shell of gutta-percha thereon, said shell to be covered with a material compounded of at least one layer of fabric and at least one layer of celluloid, said material being formed in telescoping hemispherical segments and compressed upon the ball.

13. A playing-ball comprising a solid core of gutta-percha covered by a sphere of soft rubber, and a shell of gutta-percha thereon, said shell being covered with a material compounded of at least one layer of fabric and at least one layer of celluloid, said material being cemented and the celluloid permeating the fabric; and said cover being made in telescoping segments and compressed upon the ball.

14. A playing-ball comprising a yielding filling and a shell, the latter including lap-jointed sections of fabric and plastic material, and said filling being held under compression by said shell.

15. An elastic playing-ball comprising a shell having lap-jointed sections of fabric and celluloid, and a filling of yielding material held under compression by said shell.

698,518. GOLF-BALL. BRADEN KEMPWELL, Boston, Mass., assignor to the Kampsell Manufacturing Company, a Corporation of New Jersey. Filed Mar. 24, 1902. Serial No. 99,999. (No model.)

Claim.—1. A ball consisting of a shell having apertures, and a filling secured thereto by the penetration of said filling into said apertures.

2. A ball consisting of a shell of plastic material having apertures, and a filling having integral ribs entering said apertures.

3. A ball consisting of a shell of celluloid, having apertures, and a filling interlocked therewith.

4. A ball consisting of a shell and a filling, said shell consisting of welded segments, each having apertures penetrated by parts of the filling.

5. A ball consisting of a shell, and a filling of gutta-percha interlocked therewith.

6. A ball comprising a sphere and a shell of plastic material and fabric keyed thereon.

7. A ball consisting of a filling of plastic material compressed by a shell which is formed of plastic material and fabric and is provided with openings into which the material of the filling is forced.

8. A ball consisting of a filling of gutta-percha interlocked with a shell, consisting of welded segments of celluloid and fabric and having openings which are engaged by ribs upon said filling.

9. A ball consisting of a springy sphere and a shell of plastic material, one of said elements having perforations and the other having ribs engaging therewith.

10. A ball consisting of a sphere of springy material and a shell of celluloid and fabric compressed and keyed thereon.

11. A ball consisting of a shell made of celluloid and a fabric, and a sphere of gutta-percha upon which said shell is keyed.

12. A ball consisting of a shell of celluloid lined with fabric, and a sphere upon which said shell is keyed.

13. A ball comprising two spheres, one having perforations and the other having ribs which interlock with said openings.

698,514. GOLF-BALL. BRADEN KEMPWELL, Boston, Mass., assignor to the Kampsell Manufacturing Company, a Corporation of New Jersey. Filed Mar. 24, 1902. Serial No. 99,717. (No model.)

Claim.—1. In a playing-ball, a shell made up of layers of gutta-percha, one of said layers being formed of jointed spherical segments, and another of said layers reinforcing the joint.

2. In a playing-ball, a shell comprising a plurality of layers of gutta-percha, one of said layers being formed of jointed or welded hemispherical segments, and another of said layers reinforcing the joint.

3. In a playing-ball, a shell comprising two layers of gutta-percha, each consisting of jointed spherical segments, the joint or seam in one layer running crosswise of the joint or seam in the other layer.

4. In a playing-ball, a shell comprising an inner and outer layer, both made of gutta-percha, and each consisting of a plurality of welded segments, each of said layers reinforcing the joint of the other.

5. In a playing-ball, the combination with a core of soft rubber, of a shell of gutta-percha comprising at least one layer made up of jointed segments and reinforced at the joint by another layer, said shell holding said core under compression.

6. In a playing-ball, the combination of a yielding core of soft rubber, and a shell of gutta-percha holding said core under compression, said shell comprising a plurality of layers, each of said layers consisting of segments welded together and the joint in one of said layers running crosswise of the joint in the other.

7. In a playing-ball, a shell of gutta-percha made up of layers, one of said layers being formed of jointed spherical segments and another of said layers reinforcing the joint, and a yielding core of soft rubber held under compression by said shell.

8. In a playing-ball, a shell of gutta-percha, comprising two layers, each consisting of jointed spherical segments, the joint or seam in one layer running crosswise of the joint or seam in the other layer, and a yielding core of soft rubber held under compression by said shell.

698,515. GOLF-BALL. BRADEN KEMPWELL, Boston, Mass., assignor to the Kampsell Manufacturing Company, a Corporation of New Jersey. Filed Mar. 24, 1902. Serial No. 99,991. (No model.)

Claim.—1. A playing-ball comprising a hard sphere and undivided segments of soft rubber drawn together upon said sphere so that their edges meet, said edges being caught together.

2. A playing-ball comprising a hard sphere and undivided segments of soft rubber drawn together upon said sphere and cemented together at their edges.

3. A playing-ball comprising a hard sphere and undivided segments of soft rubber drawn together upon said sphere and cemented thereon, and also cemented together at their edges.

4. A playing-ball comprising a hard sphere of gutta-percha and undivided hemispheres of highly-vulcanized soft rubber cemented to said sphere and drawn together thereon until their edges meet, said edges being cemented together.

5. A playing-ball comprising a sphere, undivided segments of elastic material drawn together upon said sphere, so that their edges meet, and a shell of relatively harder material upon said segments.

6. A playing-ball comprising a hard sphere, undivided segments of soft rubber drawn together upon said sphere and having their edges caught together, and a shell of plastic material upon said segments.

7. A playing-ball comprising a sphere of gutta-percha, undivided thick segments of soft rubber cemented upon said sphere and drawn together thereon and having their edges caught together, and a shell of celluloid upon said segments.

8. A playing-ball comprising a hard sphere, undivided segments of soft rubber drawn together upon said sphere and having their edges joined, and a shell of plastic material holding said segments under compression.

9. A playing-ball comprising a sphere of hard, springy material, undivided hemispherical segments of soft rubber drawn together upon said sphere, and a shell consisting of welded hemispherical segments of celluloid holding said soft rubber under compression.

10. A playing-ball comprising a core and undivided hemispherical segments of elastic material drawn together upon said core and caught at their edges, forming a ball whose diameter is less than that of said segments in their original or unextended condition.

11. A ball comprising a core and undivided hemispherical segments of soft rubber drawn together upon said core and caught at their edges and cemented to said core, forming a ball whose diameter is less than that of said segments in their original or unextended condition, and a shell of harder material upon said segments.

698,516. PLAYING-BALL. BRADEN KEMPWELL, Boston, Mass., assignor to the Kampsell Manufacturing Company, a Corporation of New Jersey. Filed Mar. 24, 1902. Serial No. 99,992. (No model.)

Claim.—1. A playing-ball having a core and a shell thereon, said shell consisting of fabric and plastic material and having internal ribs or teeth which engage said core.

2. A playing-ball having a sphere of gutta-percha and a casing of celluloid thereon; said casing having internal ribs which penetrate the gutta-percha.

3. A playing-ball having a sphere of gutta-percha and a casing of celluloid and fabric thereon; said casing having internal ribs which penetrate the gutta-percha.

4. A playing-ball comprising a rubber sphere, gutta-percha sphere thereon, and a casing upon said gutta-percha sphere; said casing consisting of celluloid and fabric and having internal ribs which penetrate said gutta-percha, and both said gutta-percha and said celluloid being compressed upon said rubber sphere.

698,517. PLAYING-BALL. BRADEN KEMPWELL, Boston, Mass., assignor to the Kampsell Manufacturing Company, a Corporation of New Jersey. Original application filed Mar. 15, 1902. Serial No. 99,993. Divided and this application filed Mar. 24, 1902. Serial No. 99,994. (No model.)

Claim.—A playing-ball consisting of a solid sphere of compressed gutta-percha whose internal strains have been substantially eliminated.

698,518. ADJUSTABLE ROOF OR COVER FOR TRAIN-CARS. FRANKLIN KEMMERER, Lehigh, England. Filed Jan. 21, 1902. Serial No. 99,997. (No model.)

Claim.—1. An adjustable cover or roof for the outside ends of train-cars, consisting of two or more arched standards carried by the car-body, a series of waterproof shutters adapted to be guided at their ends in or on the said standards, and to be lowered into a stowed position one behind the other alongside a side board or panel forming the permanent side to the top deck of the car-body, means for making a rain-proof joint at the junction of the shutters and fastening devices for causing the shutters to one another when in their elevated position, substantially as described.

2. In an adjustable cover or roof for the outside ends of train-cars, in combination, a permanent side or panel on each side of the upper deck of the car-body, two or more arched standards carried by the car-body extending transversely across same, a series of movable waterproof shutters and a series of movable flexible waterproof shutters, adapted to be guided at their ends in or on the said standards so that they rest on each other in their extended form and can be lowered into a stowed position one behind the other alongside the said permanent side, means for making a rain-proof joint at the junction of the shutters and waterproof shutters one with another, and fastening devices for causing the shutters to one another when in their elevated position, substantially as described.

3. In combination with a car-body, standards extending up from the body, a permanent side board at the lower part of the said standards, a box or pocket alongside the permanent side board, a removable panel having windows and adapted to fit on the permanent side board, and a flexible cover adapted to fit removably on the removable panel, the said removable cover and panel being adapted to be stowed side by side on edge within the said box, substantially as described.

698,519. GAS-BURNING HEATER. ALEXANDER W. KING, Boston, Mass. Filed June 3, 1902. Serial No. 100,001. (No model.)

Claim.—1. The described heater comprising the gas-burning chamber and a multiplicity of closely-set annular burners of uniform height, each consisting of the concentric tubes F and G erected respectively in its particular position in the upper and lower plates of the chamber, each tube G being threaded at its top, rising through the chamber common to all, and mechanically held central within the corresponding tube F, the outermost of such tubes extending terminally over the other, and one being adjustable vertically, relatively to the other, to vary the annular discharge, substantially as set forth.

2. The improved heater consisting of the chamber A B C, and a multiplicity of uniform annular burners, comprising the series of tubes F deflected laterally at top and cut in particular in the top plate A, and the series of tubes G, beveled and mechanically held at top concentric with the tubes F and threaded in the bottom plate B, each tube G being separately adjustable vertically to vary the area of the annular gas-orifice at the top of each burner, said construction producing a single heater having a great number of distinct and separately-adjustable conical flames, grouped for use as one, substantially as set forth.

698,520. GAS BAKING AND WRAPPING MACHINE. FRED H. KRAFF and CHARLES W. BLACKWELL, Chicago, Ill. Filed May 12, 1902. Received Mar. 10, 1902. Serial No. 99,995. (No model.)

Claim.—1. In a label-folding machine the combination of a carrier adapted to support the can with the label projecting from the ends thereof, means for imparting movement to said carrier, means for applying an adhesive to the ends of the can, means for folding the projecting ends of the label onto the can and compressing said folded ends securely in place.

2. In a label-folding machine, the combination of a carrier adapted to carry the labeled can, reciprocating non-rotative hands carrying movable fingers adapted to engage and fold the projecting ends of the label onto the ends of the can and means for imparting movement to said hands.

3. In a label wrapping or folding machine, the combination of a movable carrier adapted to receive the labeled can, reciprocating hands with which the can in the carrier are brought into alignment, a series of fingers pivoted to said hands adapted to embrace the projecting ends of the label, means for reciprocating said hands and means for actuating said fingers to fold the ends of the label onto the ends of the can.

4. In a label-folding machine, the combination of a carrier adapted to receive the labeled can, means for applying adhesive to the ends of the can, reciprocating hands with which the ends of the can are brought into alignment after the adhesive is deposited thereon, movable fingers in said hands adapted to engage and fold the projecting ends of the label and carry said folded ends into contact with the adhesive on the can and means for reciprocating said hands and imparting a movement to said fingers.

5. The combination of a movable carrier, adapted to receive the labeled can, means for folding the projecting ends of the label onto the ends of the can, reciprocating compressors, with which the ends of the labeled can are brought into alignment, said compressors comprising rubber or elastic cups adapted to engage the margins of the folded ends of the label and a central block within said cups adapted to be brought forcibly into contact with the label's folded ends.

6. In a labeler and wrapper, the combination with the label-applying mechanism of the label folding or wrapping mechanism, the label-applying mechanism having a continuous movement, the wrapping or folding mechanism adapted to have intermittent movement, means connecting the label-applying mechanism with the wrapping or folding mechanism adapted to be actuated by the passage of the can from the label-applying mechanism to impart an intermittent movement to said wrapping or folding mechanism.

7. In a label-wrapping machine, the combination of a rotary carriage adapted to contain the labeled can, reciprocating rolls on each side of said carrier carrying adhesive-applying, label-folding and label-compressing devices, means for reciprocating said devices simultaneously, means for rotating the carriage intermittently to bring each can in succession into alignment with said operative devices and means for arresting the movement of said carriage while said operative devices are in action.

8. The combination of the label folding or wrapping mechanism, the continuously operating labeling mechanism, gear connecting the label-folding mechanism with the labeling mechanism, said gear being normally at rest, a lever adapted to throw said gearing into action and lever extending into the path of the rolling can whereby the passage of each

can through the labeler imparts a movement to the label-folding mechanism.

9. A label-folder comprising reciprocating hands carrying pivoted fingers adapted to embrace the projecting ends of the label, said fingers being mounted to describe a circle in said hands their free ends being adapted to swing inwardly into channels in the hand's center, a sliding collar on the stem of said hands, pivoted bars connecting said collar with said fingers and means for sliding said collar to impart a movement to the fingers, substantially as specified.

10. In a label-folding machine, the combination with the operative parts and movable carriage, of the reciprocating hands, each hand having a series of pivoted fingers flexibly set in a circle, whose free ends embrace the projecting ends of the label on the can, curved bars pivoted to the rear ends of said fingers and to a collar mounted to slide upon the stem of said hands, said collar being adapted to move with said hands and to have a movement independent thereof.

11. The combination with the label folding and compressing mechanism, of the glue-containing cylinder adapted to be brought into contact with the ends of the can, movable pistons in said cylinder, spring-actuated valves seated in the pistons of said cylinder having projecting stems which extend through the end of the cylinder whereby the valves are mounted when the cylinder are brought into contact with the ends of the can.

12. In a label-folding machine, the combination of the reciprocating adhesive applicator, folding-hands and label-compressor adapted to be reciprocated in unison, a carriage located between said reciprocating parts and adapted to contain a plurality of cans and support said cans with their ends in alignment with said reciprocating parts, means for operating said parts to cause them to act upon the plurality of cans simultaneously and means for moving said carriage to bring each can in succession into position to receive the operation of said parts.

13. In a label-folding machine, the combination with the label folding and compressing means of a carriage rotating about a central axis having a series of rollers in its periphery adapted to receive the cans and means for adjusting said rollers radially of said carriage.

14. In a label-folding machine, the combination with the adhesive-applying, label folding and compressing mechanism of the movable members for imparting a reciprocation to said mechanism, pivoted angle-levers for imparting movement to said members, a cross-head adapted to reciprocate vertically, and carry horizontally-adjustable couplings mounted on said cross-head, said couplings being movably attached to the end of said lever.

698,521. APPARATUS FOR CUTTING AND POLISHING PAPER. GEORGE STUBBS. FREDERICK B. KIMM, Boston, Mass. Filed Jan. 21, 1901. Renewed Oct. 20, 1901. Serial No. 28,631. (No model.)

Claim.—1. In an apparatus of the class described, an overhanging arm or support, a stick-holder suspended therefrom and pivoted thereto for movement about both a horizontal and a vertical axis, said stick-holder having means to hold the stick from turning.

2. In an apparatus of the class described, an arm or support, a head-block pivoted thereto to move about a vertical axis, a stick-holder pivoted to said head-block for movement about a horizontal axis, said horizontal axis being in line with and vertically underneath the pivotal support of the head-block, said stick-holder having means for supporting a stick, and means to position the stick angularly about its axis.

3. In an apparatus of the class described, a stick-holder pivoted to move about both a vertical and a horizontal axis, said stick-holder having a socket adapted to receive the end of a stick, a thumb screw to the stick intermediate its ends, said thumb screw having means to interlock with

the stick-holder whereby the stick may be positioned angularly about its axis.

4. In an apparatus of the class described, an arm or support, a vertically-adjustable head-block pivoted thereto for movement about a horizontal axis, a stick-holder pivoted to said head-block to move about a horizontal axis, said horizontal axis being in line with and vertically beneath the pivotal support of the head-block, said stick-holder having a socket adapted to receive the end of a stick, and means to position the stick angularly about its axis.

5. In an apparatus of the class described, a vertically-adjustable arm or support, a vertically-adjustable stick-holder pivoted thereto for movement about both a vertical and a horizontal axis, said stick-holder having a socket adapted to receive the end of a stick, a thumb screw to the stick intermediate its ends and said thumb screw having means to interlock the arm with the stick-holder.

6. In an apparatus of the class described a stick-holder pivoted to move about both a vertical and a horizontal axis, and having a socket adapted to receive the end of a stick, a thumb screw to the stick intermediate its ends one of said parts having a series of radial recesses, and the other of said parts having a projection to engage said recesses, whereby the stick may be turned axially and held in any adjusted position to grind the facets.

7. In an apparatus of the class described, a stick-holder pivoted to move about both a vertical and a horizontal axis, and having a socket adapted to receive the end of a stick, a thumb screw to the stick intermediate its ends, said thumb screw having a series of radial recesses, an adjustable projection on the stick-holder to engage said recesses when the stick is inserted in the stick-holder, whereby the stick may be turned about its axis, and held in any adjusted position.

8. In an apparatus of the class described, a stick-holder pivoted to move about both a vertical and a horizontal axis, and having a socket adapted to receive the end of a stick, a two-part sleeve adjustably secured to the stick intermediate its ends, one of the parts of said sleeve being adjustable about the axis of the stick relative to the other, and having at one end a series of radial recesses, a projection on said stick-holder to engage said recesses, whereby the stick-holder may be turned about its axis and held in any adjusted position.

9. In an apparatus of the class described, a vertically-adjustable stick-holder pivoted to move about both a vertical and a horizontal axis, said stick-holder having a socket adapted to receive the end of a stick, a sleeve or thumb screw secured to the stick intermediate its ends, said thumb screw having at one end a series of radial recesses, a projection on said stick-holder to be engaged by said recesses, whereby by turning the stick about its longitudinal axis the facets are positioned, and by the vertical adjustment of the stick-holder the facets may be made at different angles to the axis of the stick.

10. In an apparatus of the class described, an approximately horizontal arm mounted for swinging movement about a vertical axis, said arm being jointed intermediate its ends and having a stick-holder pivoted thereto for movement about both a vertical and a horizontal axis, said stick-holder having means to angularly position the stick about its axis.

11. In an apparatus of the class described, a post or standard, an arm vertically adjustable thereon, said arm having a hub secured over said post, an extensible collar upon which the hub rests, a stop-collar on the post supporting the extensible collar, combined with a stick-holder pivoted to the end of the arm for movement about both a vertical and a horizontal axis.

12. In an apparatus of the class described, a post, a stop-collar thereon, a sleeve secured to said stop-collar and having interior screw-threads, a rotatable bushing having exterior screw-threads engaging those of the sleeve, and an arm having a hub secured over said post and resting on said bushing, combined with a stick-holder pivotally mounted on said arm, the construction being such that by turning the bushing the height of the arm may be adjusted.

13. In an apparatus of the class described, a post or standard, an arm having a hub secured over said post, a rotatable bushing on the post upon which said hub rests, said bushing having a sleeve screw-threads thereon, whereby the said bushing may be made extensible, an adjustable stop-collar on the post upon which the sleeve rests, the extensible bushing providing means for controlling the height of the arm, combined with a stick-holder pivoted to the arm to move about a vertical and horizontal axis, said stick-holder having means to receive the end of a stick and to position the stick angularly about its axis.

14. In an apparatus of the class described, a vertically-adjustable arm or support, a head-block pivoted to the end thereof to move about a vertical axis, a stick-holder pivoted to said head-block to move about a horizontal axis, said stick-holder having a socket to receive the end of the stick, and having means to position the stick angularly about its axis to form the various facets.

15. In an apparatus of the class described, an arm or support, a head-

block pivoted to said arm to move about a vertical axis, said head-block having depending arms, a stick-holder pivoted to the said depending arms of the head-block to move about a horizontal axis, said stick-holder having a socket to receive the end of a stick, and having means to position the stick angularly about its axis to grind various different facets, said head-block having an adjustable stop-arm, and said stick-holder having a pin adapted to engage said arm to limit the downward movement of the stick.

16. In an apparatus of the class described, a stick-holder mounted for movement about both a vertical and a horizontal axis, said stick-holder having a socket provided with an adjustable socket-plate which is adapted to receive the end of a stick, said socket-plate having means to angularly position the stick about its axis, and a mark on the stick-holder cooperating with the socket-plate whereby the correct angular position of the socket-plate in the stick-holder may be determined.

17. In an apparatus of the class described, a stick-holder mounted for movement about both a horizontal and a vertical axis, said stick-holder having a socket provided with an adjustable socket-plate which is adapted to receive the end of a stick, a sleeve or thumb screw on said stick, said sleeve and socket-plate having engaging means to position the stick angularly about its axis, and means to determine the correct angular position of the socket-plate in the stick-holder.

18. In an apparatus of the class described, an arm or support, a head-block pivoted thereto to move about a vertical axis and having depending arms, a stick-holder pivoted to said depending arms to move about a horizontal axis, said stick-holder having means to hold a stick and position it angularly about its axis, said head-block having an adjustable stop-arm pivoted thereto and a scale with which said arm cooperates, and a stop-pin on the stick-holder adapted to engage said arm and limit the downward movement of the stick.

19. In an apparatus of the class described, an arm or support, a stick-holder pivoted thereto to move about both a vertical and a horizontal axis, said stick-holder having a socket adapted to receive the end of a stick, the vertical and horizontal axis of the stick-holder intersecting each other and the point of intersection being on the axial line of the socket whereby the stick supported in the socket may be swung in any direction about a fixed center of motion.

20. In an apparatus of the class described, an overhanging arm or support, a stick-holder suspended therefrom and pivoted thereto for movement about both a horizontal and a vertical axis, said stick-holder having means to hold the stick from turning, and stop devices to limit the movement of the holder about its horizontal axis.

21. A stick adapted to carry a stone at one end, and tapered at its other end, said stick presenting between its ends a series of notches, the number of notches in the series corresponding with the number of facets to be cut in one round of cuts, a pivoted stick-holder having a tapered socket to receive the tapered end of the stick, and a portion extending with said notches to restrain the rotation of the stick about its axis while a facet is being ground, said socket receiving and containing the stick yet permitting said stick to be freely withdrawn therefrom after the stone has been cut, and another like stick may be inserted in the socket.

22. A stick having one end tapered and adapted to carry a stone at its other end, a pivoted stick-holder having a tapered socket to receive the tapered end of the stick, one of said parts having a series of notches and the other a projection adapted to cooperate therewith, said notches and projection being situated between the ends of the stick and serving to hold the stick from turning during the grinding of the facets, the construction being such that the stick may be freely withdrawn from its socket after the stone has been cut, and another like stick inserted in said socket.

23. A stick having one end tapered and adapted to carry a stone at its other end, a pivoted stick-holder having a tapered socket to receive said tapered end of the stick, said stick and stick-holder having interlocking devices situated between the ends of the stick, said interlocking devices serving to hold the stick from turning during the grinding of the various facets on the stone, the construction being such that the stick may be freely withdrawn from the socket after the stone has been cut, and another like stick inserted in said socket.

24. A stick-holder having a socket-plate to receive the tapered end of a stick, and means whereby the socket-plate may be turned about its longitudinal axis in the stick, to thereby provide for increasing the number of facets which may be cut on the stone carried at the end of the stick.

698,522. DRIVING-GEAR FOR VEHICLES. RUSSELL W. KISS. 1201, Detroit, Mich. Filed Feb. 15, 1904. Serial No. 42,351. (No model.)

Claim.—1. In a vehicle running-gear, a swinging arm provided with pin in axial alignment, one of which engages the end of the axle, and the other of which engages an arm riding from the axle, a splined

on the working arm parallel with the vertical arm and adapted to engage the hub of the wheel, substantially as described.

2. The combination of an axle, a wheel having a hollow hub, said axle extending into the hollow of said hub to a point in a vertical plane through the point of contact of said wheel with the ground, a standard rising from said axle a distance from the end of the axle and extending approximately at the top to a point in said vertical plane, and a hub rod pivoted at the end of the axle and extending inward, then upward, then outward, and pivoted at the end of said standard, and a hub-plate secured to said hub rod, substantially as described.

3. In the running-gear of a vehicle, in combination with a front axle, a swinging arm arranged to support the wheel-hub and provided with pins in axial alignment on which it turns, one of said pins being inside the hub and the other outside the rim of the hub, substantially as described.

4. In combination with the front axle, an arm secured to the end thereof by a vertical pin, a brace supporting the upper end of said arm, a spindle carried by said arm, having its inner end carried by said arm and arranged to swing with said arm to an angle with the longitudinal axis of the axle, substantially as described.

698,593. MACHINE FOR LAMINATING OR HEATING MATERIAL. JOHN W. KOLBART and ALBERT J. FRANK, Chicago, Ill. Filed July 12, 1906. Serial No. 54,085. (No model.)

Claim.—1. In a machine for the purpose described, the combination of a traveling hub or carrier, a series of rotary rollers arranged across said hub and under the edge of each of which enters the hub projects and means for supporting the upper end of the hub on each side of said series of rollers immediately adjacent thereto, said upper end of the hub being unsupported and dependent directly under said rollers, substantially as set forth.

2. In a machine for the purpose described the combination of a traveling hub or carrier and two series of rotary rollers arranged thereover and the rollers of one series staggered with reference to those of the other series, substantially as set forth.

3. In a machine for the purpose described, the combination of a traveling hub or carrier, a series of rotary rollers arranged thereover and normally slightly above the plane of the upper end thereof so as not to touch the hub, and means for supporting the hub immediately contiguous to each side of said rollers, said hub being unsupported and dependent directly under said rollers, substantially as set forth.

698,594. BRAKE-BAND. JOHN A. LAMER, Hammond, Ind., assignor to the Standard Railway Appliance Company, Chicago, Ill., a Corporation of Illinois. Filed Feb. 15, 1908. Serial No. 63,504. (No model.)

Claim.—1. A metallic brake-band comprising the combination with a compression and tension member having a web provided with flanges at the edge thereof, of a fulcrum-post composed of two halves disposed on opposite sides of said members out of contact with each other and forming an interposed central slot thereby and having notches engaging said flanges, and means for securing the said parts together and in position upon the said compression and tension members, substantially as described.

2. A metallic brake-band comprising the combination with a compression and tension member having flanges, of a fulcrum-post composed of two halves disposed on opposite sides of said members out of contact with each other, and forming an interposed central slot thereby, said halves being displaced of each other, and having notches engaging said flanges, and means for securing the said parts together and in position upon the said compression and tension members, substantially as described.

3. A brake-band comprising a main member provided with a web and flange, an anchor-block 4 mounted on the upper side of said web and adjacent to the forward flange thereof, a wheel-guard 5 connected to said anchor-block, a bolt 7 extending said block to the web of the main member and engaging said guard at right angles so as to secure the same against movement relative to the anchor-block and without contact with the flange, said anchor-block having a notch 10 therein engaging the flange of the main member, substantially as and for the purpose described.

698,595. BLAST DEVICE FOR FURNACE. GARY T. LAMER, Rush City, Minn. Filed June 3, 1906. Serial No. 61,047. (No model.)

Claim.—1. The combination with a furnace, of a fan having a fan-case with a blast-tube delivering to said furnace, below the grate thereof, an impact-wheel on the fan-shaft, a cone including said impact-wheel and provided with a discharge-passage delivering into the fan-case, and exhaust-supply pipe having a discharge nozzle or end terminating in a position to discharge a jet of steam against the blades of said impact-wheel, substantially as described.

2. The combination with a furnace, of a fan having a fan-case with a blast-tube delivering into said furnace, below the grate thereof, an impact-wheel on the fan-shaft, a cone including said impact-wheel and provided with two valves discharge-passages, one of which delivers steam within and the other without the said fan-case, and a valve steam-supply pipe provided with a nozzle or discharge and terminating in a position to discharge a jet of steam into the blades of said impact-wheel, substantially as described.

698,596. INVERTER-MAN FOR HAY-STACKING. EDWARD H. LOCKMAN, JR., Harky, Pa., assignor to Hiram H. Gorman, Martin B. Harky, and Harry E. Harky, Philadelphia, Pa., trading as P. C. Gorman & Company, Philadelphia, Pa. Filed Feb. 24, 1908. Serial No. 64,085. (No model.)

Claim.—1. A conveyor for a match-machine consisting of longitudinal slatted connecting-bars and a series of transverse bars secured to the ends and consisting of slatted slat metal having a series of loops forced up from the face of the metal to form a support for the match-stick on one side and a series of guiding-edges on the face of the bars above and below the loops to form guiding-supports for the match-sticks on the other side.

2. A conveyor for a match-machine consisting of longitudinal connecting-bars and a series of transverse bars secured to the ends and consisting of slatted slat metal having a series of loops forced up from the face of the metal, to form a support for the match-stick on one side, and a series of guiding-edges on the face of the bars above and below the loops to form guiding-supports for the match-sticks on the other side, and in which the edges of the loops and the edges of the face metal back of the loops and bounding the two longitudinal guiding-supports are forced outward or away from the match held by said loops and guiding-supports.

3. A match-stick-supporting bar for a conveyor consisting of sheet metal having a bent flange for strength and having its body formed with a series of outwardly-projecting looped portions pressed outwardly from the body and having their edges facing outward as at C.

4. A match-stick-supporting bar for a conveyor consisting of sheet metal having a bent flange for strength and having its body formed with a series of outwardly-projecting looped portions pressed outwardly from the body and having their edges facing outward as at C.

5. A match-stick-supporting bar for a conveyor consisting of sheet metal having a bent flange for strength, and having its body formed with a series of outwardly-projecting looped portions pressed outwardly from the body and the metal of the body back of the loops forced outwardly in a backward direction as at A.

6. A match-stick-supporting bar for a conveyor consisting of sheet metal having a bent flange for strength and having its body formed with a series of outwardly-projecting looped portions pressed outwardly from the body and the metal of the body above and below the looped portions inwardly grooved as at E, to guide the match-stick.

7. A match-stick-supporting bar for a conveyor consisting of sheet metal having a bent flange for strength and having its body formed with a series of outwardly-projecting looped portions pressed outwardly from the body and the metal of the body above and below the looped portions inwardly grooved as at E to guide the match-stick and having their adjacent edges forced outwardly backward as at A.

8. A match-stick-supporting bar for a conveyor consisting of sheet metal having a bent flange for strength and having its body formed with a series of outwardly-projecting looped portions pressed outwardly from the body and further provided on their ends with slots D in the face, combined with notches fitting said slots and having projections for supporting the flange portions of the bar.

9. A match-stick-supporting bar for a conveyor consisting of sheet metal having a bent flange for strength, and having its body formed with a series of outwardly-projecting looped portions pressed outwardly from the body and further provided on their ends with slots D in the face, combined with notches fitting said slots and having projections for supporting the flange portions of the bar.

10. A match-stick-supporting bar for a conveyor consisting of sheet metal having a bent flange for strength and having its body formed with a series of outwardly-projecting looped portions pressed outwardly from the body and further provided on their ends with slots D in the face, in combination with carrier-bars fitting said slots, and a spring connecting the carrier-bars and holding one of the supporting-bars in position.

11. A match-stick-supporting bar for a conveyor consisting of sheet metal having a bent flange for strength and having its body formed with a series of outwardly-projecting looped portions pressed outwardly from the body, and having the ends made with notches for receiving the teeth of driving sprocket-wheels.

12. A match-stick-supporting bar for a conveyor consisting of a slatted-bar the intermediate body of which is provided with rounded projecting portions I forming apertures J, bounded on one side by said projecting portions and on the other by the body of the bar, and in which the body is grooved in alignment with the apertures to properly guide the match-stick.

13. In a conveyor for a match-machine, a section comprising the match-bars B having loops O, combined with supporting-bars for the matches, having flanges D projecting loops I and slots d into which the match-bars fit and in which the flanges D rest against the loops O of the said match-bars.

14. In a conveyor for a match-machine, a section comprising the match-bars B having loops O, combined with supporting-bars for the matches having flanges D projecting loops I and slots d into which the match-bars fit and in which the flanges D rest against the loops O of the said match-bars, and a spring G pressing against one of the supporting-bars and looped over the loops O of the match-bars for holding them in the slots d of the supporting-bars.

698,597. DEVICE FOR CLEANING LAMPS, GLASSES, OR KALEIDOSCOPES. ERNEST K. HART, Austria-Hungary. Filed May 12, 1906. Serial No. 54,034. (No model.)

April 29, 1903.

Claim.—A device for cleaning lamp-chimneys and other similar hollow bodies, characterized by a handle *a* to one end of which are attached two flat leaf-springs *b* provided with readily-movable plates *f*, fixed with pins *d* of elastic material.

688,598. JOHN W. GRAHAM, JR. AND ELEVATOR. JOHN GRAHAM and FRANK L. KAY, Attys., St. Paul, Minn., 7, 1901. Serial No. 94,381. (No model.)

Claim.—1. In agricultural machines, a tilting support, means for locking and releasing the tilting support, and a hinged platform at one end of the tilting support and held in an open position by the said locking and releasing device of the tilting support, as set forth.

2. In agricultural machines, a dumping-support, means for locking and releasing the dumping-support, a hinged platform, hinged to the dumping-support, a conveyor located beneath the hinged platform, and an elevator connected with the conveyor.

3. In agricultural machines, a dumping-support, means for locking and releasing the dumping-support, a hinged platform at one end of the dumping-support, hinged to the support, a conveyor located beneath the hinged platform, an elevator connected with the conveyor, and a slide opening at the rear portion of the conveyor at a point beneath the hinged platform, for the purpose of regulating the supply of material to the conveyor, as specified.

4. In agricultural machines, a hinged platform, a support therefor, hinged to the support, which hinged support is adapted to be raised and lowered by the hinged platform, a conveyor beneath the hinged platform, and a slide opening in the conveyor beneath the hinged platform, as specified.

5. In agricultural machines, a hinged platform, a support therefor, hinged to the support, which hinged support is adapted to be raised and lowered by the hinged platform, a conveyor beneath the hinged platform, a device against which the hinged platform rests when opened, and an elevator connected with the conveyor and adapted to be raised and lowered by the hinged platform, as specified.

6. In agricultural machines, a hinged platform, a support therefor, hinged to the support, and adapted to be raised and lowered by the hinged platform, a conveyor beneath the hinged platform, which is arranged to engage with the under face of the hinged platform, a conveyor located below the hinged platform, an elevator connected with the conveyor, and a slide opening in the conveyor, having movement beneath the hinged platform, for the purpose set forth.

7. In agricultural machines, a tilting support, means normally held in locking engagement with the tilting support, means for opening said means to move them out of engagement with said support, and a hinged platform at one end of the tilting support and engaged by the means for opening the same for holding the platform raised at the time the same are disengaged from the tilting support, as set forth.

8. In agricultural machines, a fixed platform, dumping bars or rolls

pivotedly carried by the fixed platform, a tension-controlled shaft provided with crank-arms having normal locking and supporting engagement with the dumping-bars, a second platform located adjacent to the dumping-platform, a support to which the second platform is hinged, hinged to said supports and arranged to normally rest flat thereon below the hinged platform, projections from the hinged platform adapted for engagement with the under face of the hinged platform to raise the same when the hinged platform is raised, and a conveyor located beneath the hinged platform, for the purpose specified.

9. In agricultural machines, a tilting support, a shaft provided with arms normally held in engagement with said support, a rod connected with said shaft for operating it, and provided with a projection, and a hinged platform at one end of the tilting support and provided with a stop adapted to be engaged by the projection on the operating-rod, as set forth.

10. In agricultural machines, a platform, dumping-bars mounted in the platform, a crank-shaft, the crank-arms of which are adapted to engage the ends of the said bars, a spring connected with an arm of the crank-shaft, an operating-rod connected with the crank-shaft and passing through a guide, said rod being provided with a handle at its end and with a projection between its ends, and a hinged platform at one end of the main platform and provided with a stop adapted to be engaged by the projection of the operating-rod, as set forth.

11. In agricultural machines, a platform having longitudinal openings therein extending from end to end, crank-plates secured to the platform at opposite sides of the central portion of said openings, dumping-bars located in the said openings, a shaft connected to each dumping-bar, extending from the center downward to its end, the central portion of each shaft being provided with flanges at its ends, and transverse extensions from the side portions of the said shafts, and adapted for bearing upon the crank-plates, as set forth.

12. In agricultural machines, a platform having longitudinal openings therein extending from end to end, crank-plates secured to the platform at opposite sides of the central portion of said openings, dumping-bars located in the said openings, a shaft connected to each dumping-bar, extending from the center downward to its end, the central portion of each shaft being provided with flanges at its ends, transverse extensions from the side portions of the said shafts, being adapted for bearing upon the crank-plates, a crank-shaft located beneath said platform at one end, the crank-arms of which shaft are adapted for locking and supporting engagement with the ends of the dumping-bars, a tension device for the said shaft, and means for turning the said shaft against the resistance of the tension device, as set forth.

13. In an agricultural machine, a frame, tracks secured to said frame, a conveyor having extensions from its sides adapted to rest upon the said tracks, a hinged platform located above the conveyor, hinged to the frame between the hinged platform and the conveyor, which hinged platform is adapted to drop by gravity, and means substantially as described, for raising the said hinged platform when the hinged platform is elevated, for the purpose described.

14. An agricultural machine, comprising a tilting support, a hinged platform at one end of the tilting support, hinged to the support, a platform hinged to the fixed support carrying the hinged platform and at right angle to the said hinged platform, a conveyor arranged below the hinged platform and at right angle to the tilting support, and an elevator connected with the conveyor, as set forth.

15. An agricultural machine, comprising a tilting support, a hinged platform at one end of the tilting support, hinged to the support, a platform hinged to the fixed support carrying the hinged platform and at right angle to the said hinged platform, a conveyor arranged below the hinged platform and at right angle to the tilting support, and an elevator connected with the conveyor, as set forth.

16. An agricultural machine, comprising a stationary platform, a tilting bar mounted in the platform, means for locking and releasing the tilting bar, a hinged platform at one end of the stationary platform, and held open by the tilting bar locking and releasing means, hinged to the hinged platform, a conveyor below the hinged platform, a device against which the hinged platform rests when opened, and an elevator connected with the conveyor and adapted to be raised and lowered by the hinged platform, as set forth.

17. An agricultural machine, comprising a stationary platform, a tilting bar mounted in the platform, means for locking and releasing the tilting bar, a hinged platform at one end of the stationary platform, and held open by the tilting bar locking and releasing means, hinged to the hinged platform, a conveyor below the hinged platform, a device against which the hinged platform rests when opened, and an elevator connected with the conveyor and adapted to be raised and lowered by the hinged platform, as set forth.

688,599. MATTHEW JAMES HARRISON, Ryegate, Canada. Filed June 28, 1901. Serial No. 94,714. (No model.)

Claim.—A mattress consisting of a series of interconnected springs instead of a solid casing, corresponding springs in any two series being disposed side by side, another series disposed in the space formed by said first-named springs, each smaller spring being linked to one of said first-named springs, and means for connecting said pairs of springs with each other, substantially as described.

April 29, 1903.

U. S. PATENT OFFICE.

909

688,599.

688,580. AUTOMATIC VALVE. FREDERICK E. HARRIS, Syracuse, N. Y. Filed June 24, 1901. Serial No. 94,791. (No model.)

Claim.—1. The combination with a valve, of a valve-chamber having two curved-shouldered fittings, a two-part fluid cushion, one part connected to the valve and movable therewith, and a transverse pin fitting between said cushion of the valve-chamber and rigidly secured to the lower member of the fluid cushion, substantially as specified.

2. The combination with a valve, of a valve-chamber having two curved-shouldered fittings, a two-part fluid cushion having an inner or piston member connected to the valve-chamber and having an outer or cylinder member provided with a screw-threaded cap at its upper end, said cap also forming a support or holder for the valve, substantially as specified.

3. The combination with a valve-chamber and valve, of a two-part, double-acting fluid cushion immersed in and its interior communicating with the fluid under pressure within said chamber, said fluid cushion having an outer fitted cylinder member and an inner inverted-cup-shaped piston member provided with a minute opening or vent in its upper end, substantially as specified.

4. The combination with a valve-chamber and valve, of a fluid-cushion cylinder member *D*, having opposite ends *d'* extending from its middle portion to its upper end, an inner piston member provided with a transverse pin secured to the valve-chamber, substantially as specified.

5. The combination with a valve-chamber and valve, of a fluid-cushion cylinder member *D*, having opposite ends *d'* extending from its middle portion to its upper end, and an inner piston member provided with a transverse pin secured to the valve-chamber, said outer cylinder *D* having a removable screw-threaded cap forming also a holder for the valve, substantially as specified.

6. The combination with a valve-chamber and valve, of a fluid-cushion cylinder member *D*, having opposite ends *d'* extending from its middle portion to its upper end, an inner piston member provided with a transverse pin secured to the valve-chamber, said outer cylinder *D* having a removable screw-threaded cap forming also a holder for the valve, and provided with screw-threads for connection with the valve-rod, substantially as specified.

7. The combination with a valve and valve-chamber, of a valve-rod, a knob for reciprocating the valve-rod furnished with a flange telescoping on the valve-chamber, and a lock-bolt and key, substantially as specified.

8. The combination with a valve, of a valve-chamber having two curved-shouldered fittings, a double-acting two-part fluid cushion, connected one part to the valve-chamber and one part to the valve, and a valve-rod fitted in the lower fitting of the valve-chamber, substantially as specified.

9. The combination with a valve, of a valve-chamber having two curved-shouldered fittings, a double-acting two-part fluid cushion, connected one part to the valve-chamber and one part to the valve, and a valve-rod fitted in the lower fitting of the valve-chamber, substantially as specified.

10. The combination with a valve and valve-chamber, of a valve-chamber

having two curved-shouldered fittings, a transverse pin between the meeting ends of the cushion, a fluid-cushion piston secured to said pin, a reciprocating fluid-cushion cylinder having longitudinal slots to receive said pin, a removable screw-threaded cap closing its upper end and to receive said valve and to receive the threaded end of the valve-rod, said valve-chamber being provided with an integral collar or shoulder to hold the valve in place on said cap, substantially as specified.

11. The combination with a valve and valve-chamber, having two curved-shouldered fittings, and provided with a valve-chamber, a contracted outlet-channel, a delivery-chamber, a drainage-chamber and a drainage-channel terminating in said delivery-chamber adjacent to and at the mouth of said contracted outlet-channel, and a screw-plug closing said drainage-chamber, and provided with a spring-chamber and spring to act against the valve-rod, substantially as specified.

688,581. CASTING ROLL OR ROLLING CIRCULAR DOCK. SAMUEL HENRIKSON, Chicago, Ill. Filed Mar. 14, 1901. Serial No. 91,992. (No model.)

Claim.—1. A flask composed of two sections, a transverse on each section, internal longitudinal bars secured in each section, mold-retaining diaphragms having free ends conforming to the molding-surfaces secured to each longitudinal bar, an end plate at each end of each section provided with a half-bearing, two end plates cooperating to form an end bearing, and a core or other rod held in the bearings thus formed, substantially as described.

2. A flask composed of two sections, internal longitudinal bars secured in each section, mold-retaining diaphragms having free ends conforming to and protruding the surface of the mold, end plates at each end of each section provided with a half-bearing and one of the end plates of each section provided with a cut-away portion for the runner-opening, and a core or other rod adapted to be held in the bearings formed by the cooperation of the end plates, substantially as described.

3. The combination with a casting-pit, a bearing on each side thereof of end hinged covers for closing the same, of a pipe-flask composed of two longitudinal sections, a half-transverse on each side of each section, and plates one of which is provided with a screw-bearing, means for supporting the flask in a vertical position in the pit, and brackets vertically hinged to a wall of the pit and arranged to be swung laterally under the ends of the flask after it has been rotated to maintain it in horizontal position, substantially as described.

4. The combination with a casting-pit, of a pipe-flask comprising two longitudinal sections having vents, means to rotatably support said flask in the pit, internal bars in each section and diaphragms secured to said bars to hold the mold in the flask, and end plates on each end of each section and provided with bearings to support a core and to center a former-board during the filling of the flask, substantially as described.

5. The combination with a casting-pit, and a flask rotatable in the casting-pit and comprising two halves, each provided with longitudinal bars *G* and diaphragms *g*, an end plate on each half of the flask provided with a half-bearing cooperating when the flask is set up to form a central bearing at each end; of a shaft extending through the flask and the central bearings at the ends, a former-board rigidly connected to the shaft and means for rotating the shaft and former-board, substantially as described.

6. The combination with a casting-pit, of a flask rotatable therein comprising two halves, provided with lines of vents, longitudinal bars secured to the flask between the lines of vents, and diaphragms secured at one end to the longitudinal bars and having free ends bent at an angle and conforming to the molding-surfaces, an end plate on each end of each half-flask provided with a half-bearing cooperating when set up, to form a central bearing to centrally support a suitable core.

688,582. TRAILER-CONTROLLER. PERCY B. HILLIOT, Buffalo, N. Y., assignor to Automatic Trailer Controller and Controller Company, Syracuse, N. Y., a Corporation of New York. Filed Mar. 24, 1901. Serial No. 92,993. (No model.)

Claim.—1. A trailer-controller comprising a support, an extensible spring having its lower end fixed to the support from end-to-end movement and its other end movable vertically, means connected to the free end of

the spring for extending and tensioning the same vertically, a catch mounted on said free end of the spring for interlocking with a portion of the support and holding the spring tensioned, and an opening-cord or its equivalent connected to the catch whereby the sudden tensioning of the cord operates to release the catch and spring for the purpose specified.

2. A trolley-controller comprising a support, an extendible spring having its lower end pivoted to the support and fixed from endwise movement and its other end movable, means connected to the upper end of the spring for tensioning the same, a catch mounted on the free end of the spring and adapted to interlock with the support for holding the spring tensioned, and an opening-cord or its equivalent connected to the catch and to the trolley-arm whereby the sudden tensioning of the cord operates to release the catch and spring for the purpose specified.

3. A trolley-controller comprising a support, a spring having its lower end fixed from endwise movement and its other end adapted to be extended or tensioned vertically, means for extending the spring, a catch mounted on the free end of the spring and arranged to automatically interlock with a portion of the support when the spring is tensioned, a cleave connected to the catch, and a cord connected to the support and cleave and adapted to be connected to the trolley-arm, said catch and spring being released by the sudden tensioning of the cord for the purpose specified.

4. The combination with a support, a trolley-arm-opening cord or its equivalent, and a take-up device for the cord, of a spring fixed at one end from endwise movement and having its other end extendible vertically and provided with a spring-extended catch for engaging the support and holding the spring tensioned, said catch being released by the cord as and for the purpose specified, and means for extending or tensioning the former spring.

5. The combination with a support and an automatic take-up device for the trolley-arm-opening cord, a spring having one end pivoted on the support and its other end extendible and provided with independent cleaves one being engaged by the trolley-arm-opening cord, a flexible member connected to the other cleave for tensioning the spring, and a catch connected to the former cleave for engaging the support and holding the spring in its tensioned position, said former cleave being movable by the cord for releasing the catch and spring.

6. The combination with a support, a trolley-arm-opening cord or its equivalent, and a spring having one end fixed from endwise movement and its other end extendible and provided with a cleave, a take-up drum mounted on the support, a flexible member connected to the take-up cord to the cleave whereby the spring may be tensioned, and a catch for holding the spring tensioned, said catch being connected to the opening-cord of the trolley-arm for the purpose specified.

7. The combination with a support having its opposite ends provided with bearings, one being adjustable toward and away from the other, a cleave having a hook connected with one of the bearings, a take-up drum mounted on the bearings and provided with a centrifugally-actuated pawl adapted to engage the teeth of the hook as described, and a trolley-arm-opening cord connected to the drum.

8. The combination with a support and a take-up device for the trolley-arm-opening cord, a cord connected to the support, a spring

having its lower end fixed from endwise movement to the support, and its upper end extendible and provided with a catch for engaging the support and holding the spring tensioned, a second take-up drum between the spring and former drum, and flexible means connected to the second drum and to the upper end of the spring for tensioning the spring.

9. In a trolley-controller, the combination with a support having separated bearings, one being adjustable toward and away from the other, a spring-extended take-up drum adjustably mounted on said bearings, and a trolley-arm-opening cord connected to the drum.

10. In a trolley-controller, the combination of a support having separated walls one being provided with a ball-bearing and the other being removable and provided with an adjustable cone-bearing, and a variable spring-extended take-up drum mounted on the bearings and having one end of a trolley-arm-opening cord connected thereto.

11. The combination with an inclining one or frame having lower engaging shoulder, an extendible spring within the frame and having its lower end fixed thereto from endwise movement and its upper end provided with a catch adapted to engage the shoulder when the spring is extended, means connected to the upper end of the spring for tensioning the same, and a take-up device supported in the frame and connected to the opening-cord of the trolley-arm, said cord being connected to the catch for effecting the release of the spring and the spring curving to draw the cord downwardly.

12. In a trolley-controller the combination of an inclining one or frame having an engaging shoulder, an extendible spring having one end fixed from endwise movement to a pivot and its other end movable and provided with a catch for engaging said shoulder and holding the spring tensioned, independent cleaves connected to the upper end of the spring and movable therewith, one of the cleaves being movable vertically independently of the spring, independent take-up drums mounted on the frame, a cord or its equivalent engaged with the lower free end of the cleave connected to the catch and having one end connected to one of the drums and its other end adapted to be connected to the trolley-arm, and a second cord or its equivalent engaged with the lower free end of the other cleave and having one end connected to the other drum and its other end provided with a handle for the purpose set forth.

698,588. WIRE-FENCE MACHINE. ARTHUR C. HALL, Boston, and GEORGE E. LAM, Boston, Mass. Filed Dec. 12, 1904. Serial No. 58,700. (No model.)

Claim.—1. In combination with means for holding round wire, oppositely-moving frames adapted to pass at the respective sides of one of said wires, grippers moving transversely to the movement of the frames, and means for operating the frames and grippers, substantially as described.

2. In combination with means for holding round wire, an oppositely-moving frame, horizontally-acting grippers, a downwardly-acting former and means for operating the frames and grippers, substantially as described.

3. The combination of spring-extended pressure to hold round wire and a staple-shaped fastener, an oppositely-acting reciprocating frame, horizontally-acting grippers, a downwardly-acting reciprocating former, and means to operate the frames and grippers, substantially as described.

4. In combination with means for holding round wire and a staple-shaped fastener, a former moving at each side of one of said wires to bend the ends of the staple in one direction, grippers moving toward and

other to cross the ends of the fastener, a former acting oppositely to the first-mentioned former to bend the ends of the staple in the other direction, and means for operating said frames and grippers, substantially as described.

5. The combination of a pair of rolls, means for rotating the rolls simultaneously, a spring-extended pressure in one of the rolls, radially-acting and oppositely-acting frames in the respective rolls, transversely-acting grippers mounted on the rolls, and non-rotating cams to operate the frames and grippers, substantially as described.

6. The combination of a pair of rolls having circumferential and transverse grooves to engage round wire, radially-acting frames on the respective rolls adapted to operate in succession and in opposite directions, a pair of transversely-acting grippers pivoted on one of said rolls and operating intermittently of the frames, and means adapted to operate the frames and grippers, substantially as described.

7. The combination of a pair of rolls having circumferential and transverse grooves to engage round wire, spring-extended pressure in the upper roll to engage the wire and a fastener-blank, a radially-acting former in the lower roll, grippers pivoted on the upper roll, a radially-acting former in the upper roll, non-rotative cams to operate the frames and grippers, and means for adjusting and holding the same, substantially as described.

8. The combination of a pair of rolls adapted to engage round wire, frames and grippers for bending the fasteners mounted on said rolls, non-rotative cams for operating said frames and grippers, means for supplying fasteners to the rolls, a second pair of rolls, finishing-dies in the last-mentioned rolls, and means for synchronizing the rotation of the respective pairs of rolls, substantially as described.

9. In combination with a pair of rolls adapted to engage round wire, a detachable block in one of said rolls, and reciprocating frames and pressure extending through said block, and retained in place thereby, substantially as described.

10. The combination of a pair of rolls having fastener-forming means attached, a second pair of rolls having finishing-dies attached, worm-gearing to drive each separate pair of rolls, separate shafts to operate the respective worm-gears, a collar on one shaft having an annular T-slot, a collar on the other shaft having openings, and bolts passing through the openings in said collar and having heads adjustably engaging the T-slot in the other collar, substantially as described.

11. The combination of a pair of rolls having circumferential and transverse grooves, spring-extended pressure in the upper roll to engage the wire and a fastener, radially-acting frames in the lower roll having outwardly-projecting studs, non-rotating cams engaging the studs, means for adjusting said cams, grippers pivoted on the upper roll, radially-acting slides in said roll and having outwardly-projecting studs, rods connecting the slides and grippers, non-rotative cams engaging the studs, means for adjusting said cams, a radially-acting former in the upper roll and having a bifurcated outer end and laterally-projecting studs, and projections on the last-mentioned cam to engage the said studs, substantially as described.

12. The combination of a pair of rolls having circumferential grooves to engage a longitudinal wire, a hook on the lower roll to engage a transverse wire, a die to convey staple-shaped fasteners, a shaft near the die, a spur-wheel on the shaft and engaging the fastener, a ratchet-wheel on said shaft, a reciprocating pawl engaging said wheel, and a cam to operate the pawl, substantially as described.

13. The combination of a pair of rolls, reciprocating frames and grippers mounted on said rolls, non-rotating and adjustable cams to operate the frames and grippers, rolls pivoted to the same at one end, and extending through fixed plates at the other ends, and adjusting-screws on said rolls, whereby the same are adjusted, substantially as described.

14. In a wire-fence machine the following means for feeding and attaching a fastener: a spring-extended pressure to hold the fastener-blank, a reciprocating former to bend the ends of the blank laterally in one direction, another reciprocating former to bend the ends of said fastener laterally in the opposite direction, a pair of grippers to cross the ends of the fastener after the first bending and before the second bending, a pair of finishing-dies to finish the ends of the fastener and finish drawing the fastener, and means for operating the frames, grippers, and dies, substantially as described.

698,584. PROCESS OF MANUFACTURING GLASS. LOUIS A. HARRIS, Park, France. Filed June 10, 1900. Serial No. 23,812. (No model.)

Claim.—The hot-blast method of treating glass consisting in first treating the glass, pressing and heat spreading on the same upon supporting-plates, third, subjecting it to a vacuum in a drawing temper-

ture, and finally raising the temperature to draw the glass and compress the surface thereon, substantially as described.

698,585. COTTON-FLICKEER FOR FORMING MATTRESS-BATS. JOHN W. HERRMAN, San Antonio, Tex., assignor, by direct and mesne assignments, to the Tennessee Pat. Manufacturing Company, West Nashville, Tenn. Filed Apr. 25, 1906. Serial No. 573,002. (No model.)

Claim.—In a machine of the class described, the combination of an endless traveling feed-apron, rollers thereon extending therewith to form and feed a bat, an inclining casing having a feed-opening on one side, a delivery-opening on the opposite side provided with a spout, an air-inlet bottom opening and an inclined board between said air-inlet opening and said delivery-opening, feed-rollers to which the bat is delivered and located in said feed-opening, a picker-roller coacting with said feed-rollers to draw the bat therefrom, disengage the bat and draw the fibers therefrom, and a reversible blast-cylinder disposed in operative relation to the picker-roller, on the side thereof opposite the feed-rollers and over the said inclined board, said blast-cylinder having peripheral straightening-blades to draw the fibers from the picker-roller and beat the same on and along the inclined board, and create a blast to carry said beaten and straightened fibers through said discharge-spout, substantially as described.

698,586. SAWBOW. JOHN E. HURLEY, Oak, Ark. Filed Oct. 2, 1904. Serial No. 77,908. (No model.)

Claim.—1. In a sawbow, the combination with a beam having a recess in one side thereof of a beveled strip secured to the beam and having a recess therein adapted to register with the recess in the beam; a cleave; a shaft thereto having grooves in opposite sides thereof adapted to receive the walls of the recesses.

2. In a sawbow, the combination with a beam, of strips secured one to the other and to the beam, means formed between the extending flange of the strips and beam, studs having grooves in the side thereof and engaging the walls of the recesses, cleaves to the studs, and beam.

3. In a sawbow, the combination with a beam, of a standard extending upward therefrom, a horizontal cross-bar to the standard, handles secured to the beam and to the beam, a series of strips secured one to the other, said strips being attached to one side of the beam, apertures formed between the extending flange of the strips and beam, a cleave in each aperture, said cleave having grooves in its side engaging the walls of the apertures, a cleave to each stud, and means connecting the studs and strips and beam.

698,587. METAL SHELL-BAND LAMP. JAMES HERRICK, JR., and LOUIS C. HERRICK, Cincinnati, Ohio. Filed Oct. 25, 1901. Serial No. 59,000. (No model.)

Claim.—1. A shell-metal shell-band provided with an internal supporting-spring having forward therein a spiral thread extending from its outer end and to its inner free end, substantially as set forth and for the purpose specified.

2. The combination with a shell-metal band, of a detachable shell-

metal shell-band adapted to be driven thereon, an internal threaded resilient flange upon the outer end of said sheet-metal shell-band and a dent and mud cap adapted to be received therein, substantially as set forth.

2. A sheet-metal shell-band formed with a series of pyramidal knobs upon the outer circumference of the band, substantially as set forth.

4. A threaded cap having a knurled edge, the outer surface of the cap bulging outwardly toward the center and a circular row of pyramidal knobs arranged around said bulged portion and between the same and the knurled edge, substantially as set forth.

5. A sheet-metal shell-band having a threaded portion in combination with a cap having threads adapted to engage therewith and a nut formed integral with said cap for turning the same.

698,588. CLAMP FOR PNEUMATIC HAMMERS. ALBERT G. HENRY, East St. Louis, Ill., assignor to Standard Railway Equipment Company, a Corporation of Illinois. Filed May 17, 1901. Serial No. 92,004. (No model.)

Claim.—1. A clamp for pneumatic hammers comprising clamping-jaws and a resilient split ring controlling them, said jaws being adapted to be mounted upon a pneumatic hammer, substantially as described.

2. A clamp for pneumatic hammers comprising two semicircular clamping-jaws and a spring controlling them, said clamp being adapted to be mounted upon a pneumatic hammer, and shoulders on their inner faces adapted to interlock with devices provided thereon on the shank of a tool in said hammer, substantially as described.

3. The combination with a pneumatic hammer having a circumferential groove at its front end, and a tool fitting in the front end of said hammer and having a circumferential rib overlapping the end of said groove, of a clamp comprising semicircular clamping-jaws having flanges fitting in said groove and having shoulders interlocking with said rib, substantially as described.

4. The combination with a pneumatic hammer having a circumferential groove at its front end, and a tool fitting in the front end of said hammer and having a circumferential rib overlapping the end of said groove, of a clamp comprising semicircular clamping-jaws having flanges fitting in said groove and having shoulders interlocking with said rib, the distance between the front end of the cylinder and the shoulder of the clamping-jaws being greater than the width of the interlocking rib of the tool, whereby said tool is free to move longitudinally, substantially as described.

5. The combination with a pneumatic hammer having a circumferential groove at its front end, and a tool fitting in the front end of said hammer and having a circumferential rib overlapping the end of said groove, of a clamp comprising semicircular clamping-jaws having flanges fitting in said groove and having shoulders interlocking with said rib, the

edges of the shoulders of the clamping-jaws being beveled, substantially as described.

698,589. ROTARY ENGINE, WATER-METER OR PUMP. THOMAS C. MCGRAW, Philadelphia, Pa. Filed May 20, 1901. Serial No. 92,005. (No model.)

Claim.—1. In a rotary engine, motor or pump, a casing or cylinder, a plurality of shafts rotatably mounted therein, a plurality of pumping units mounted on said shafts, each of said units consisting of one or more rotary pistons, each provided with a single vane and one or more abutment-pieces, each provided with a single gap, the vanes and gaps of said different units being so located that the vanes on one shaft shall be opposite the gaps on the other shaft so that said units will not cause pumping at the same instant.

2. In a rotary engine, motor or pump, the combination of a casing having a section-opening in its lower portion, a channel extending longitudinally in the lower portion of said casing, piston-chambers located above said channel, ports extending upwardly from the ends of said channel to said chambers, a plurality of shafts passing through said piston-chambers, and a plurality of units mounted on said shafts between said ports, each of said units consisting of a rotary piston provided with a vane and an abutment-piece having a gap, and each of the half-units being placed in longitudinal juxtaposition, but at a varying angle on each shaft and the pistons on one shaft being arranged opposite the gaps upon the other shaft and in each relative position that the vanes shall mesh with the gaps on the opposite members as the shafts rotate, whereby each pair of opposing members constitutes a pumping unit, whereby said units will not be at the inspirative point at the same instant.

3. In a rotary engine, motor or pump, the combination of a casing having a section-opening in its lower portion, a channel extending longitudinally in the lower portion of said casing, ports extending upwardly from the ends of said channel, piston-chambers located above the lower channel, a plurality of shafts passing through said piston-chambers, a discharge-outlet for said casing, and a plurality of half-units mounted on each of said shafts, each of said units consisting of a rotary piston with a vane, and a rotary abutment-piece with a gap, each of said half-units being placed in longitudinal juxtaposition but at a receding angle on each shaft and the pistons on one shaft arranged opposite the gaps of the members on the other shaft and in each relative position that the vanes shall mesh with the gaps on the opposing members as the shafts rotate, whereby each pair of opposing members constitutes a pumping unit, whereby water is forced from said ports toward said discharge-outlet and the vanes and gaps of the different units will not cause pumping at the same instant, whereby the water instead of passing in the next unit at a slight angle is carried substantially one-half way around the shaft before meeting the preceding vane.

4. In a rotary engine, motor or pump, a casing or cylinder, a plurality of shafts rotatably mounted therein, a plurality of independent units mounted on said shafts, each of said units consisting of a rotary piston having a single vane detachably connected thereto and an abutment-piece provided with a single gap, said vanes and gaps being so located with respect to each other with the pistons on one shaft arranged opposite the gaps of the opposing members on the other shaft and in each relative position that the vanes shall mesh with the gaps on the opposing members as the shafts rotate whereby each pair of opposing members constitutes a pumping unit, so that they will not be at the inspirative point at the same instant.

5. In a rotary engine, motor or pump, a cylinder, a plurality of shafts rotatably mounted therein, each of said shafts being provided with pumping units having abutments with gaps cast roughly therein, the outer peripheries of said abutments and the spaces alternating between said abutments being finished and vanes detachably secured in position on the finished portions between said abutments, the pistons on one shaft being arranged opposite the gaps of the members on the other shaft in each relative position that the vanes shall mesh with the gaps as the shafts rotate whereby each pair of opposing members form a pumping unit.

6. In a rotary engine, motor or pump, a plurality of shafts having pumping units thereon, said units consisting of abutments having gaps cast therein, the outer peripheries of said abutments being turned or finished and the alternating spaces between said abutments being also finished, the spaces between said abutments being provided with vanes detachably secured therein, said vanes and gaps being arranged so that each gap when not in mesh with the corresponding vane will serve as a passage through which the next preceding pumping unit in the series shall deliver and adapted to meet, whereby the pumping action of each group of units will not cease at the same instant.

7. In a rotary engine, motor or pump, a cylinder or casing, a plurality of shafts rotatably mounted therein, and a plurality of pumping members on each of said shafts, consisting of rotary pistons, and disks on each shaft alternately between the pistons, said pistons and disks being provided respectively with a vane and a gap permitting each vane to carry the water through the gap substantially one-half way around the shaft before meeting the next adjacent vane.

8. In a rotary engine, motor or pump, a cylinder or casing, a plurality of shafts rotatably mounted therein, and a plurality of pumping members on each shaft, consisting of rotary pistons, and disks on each shaft alternately between the pistons, said pistons and disks being provided respectively with a vane and a gap permitting each vane to carry the water through the gap substantially one-half way around the shaft before meeting the next adjacent vane, said vanes being disposed in series in moving from whereby leakage past one vane is prevented by the next succeeding vane.

9. In a rotary engine, motor or pump, the combination with a casing, of a plurality of shafts rotatably mounted therein, a series of alternating vane-pieces and disks provided each with a gap upon each shaft, the pistons on one shaft being arranged opposite the disks upon the other shaft and in each relative position that the vanes shall mesh with the gaps in the disks as the shafts rotate, whereby each pair of opposing pistons and disks constitutes a pumping unit, supply and discharge passages communicating with the casing, the former arranged to deliver fluid to the first pumping unit and the latter arranged to receive it from the last pumping unit, the gap in each disk serving, when not in mesh with the corresponding vane, as a passage through which the next preceding pumping unit in the series shall deliver.

698,540. AUTOMATIC SELF-CLOSING FIRE-DOOR. GEORGE H. MCGRAW, New York, N. Y. Filed Apr. 5, 1901. Serial No. 91,516. (No model.)

Claim.—1. In combination with a door adapted when released to close automatically, a latch adapted to secure the door and normally held open; a hand-pull; a connection between the latch and the hand-pull for releasing the door; a projection upon this connection; and a sliding hand-operated member having a projection coacting with the projection on the connection and adapted to engage and operate said releasing connection.

2. In combination with an opening into a shaft and a self-closing door therein, a gravity-latch for normally holding the door open; a pulley mounted convenient to said opening; a fireproof cord secured to said latch and extending over said pulley; a projection on said cord; a ball-crank lever having one arm secured to the other end of said cord and mounted in said shaft; a hand-pull secured to the outer end of said ball-crank lever and conveniently located outside said shaft; and hand-operated means having an eye lowered by said cord and adapted to engage the projection thereon to operate the latch.

3. A series of self-closing doors, gravity-latches for normally holding said doors open; fireproof cords attached to each of said latches and extending over one of said pulleys; a hand-pull secured to each cord; a fireproof cord secured to each door and extending over another of said pulleys and having its end secured to a counterweight; a sliding member extending alongside said openings from the upper to the lower end thereof, said member provided with eyes adapted when said member is lowered to engage the hand-pull cords; and a wire having a weight at one end and extending horizontally across said openings and having its upper end connected to said sliding member and adapted to hold said sliding member in its highest position, said wire having tubular links in its horizontal portion.

4. The combination with a shaft, of ways alongside the openings into said shaft; doors sliding in said ways; means for normally holding said doors open; hand-operated means for releasing each of said holding means; hand-operated means for simultaneously releasing all of said holding means; and hand-operated means for releasing said doors through the hand-operated releasing means.

5. The combination with a series of doors, one above the other and adapted when released to close automatically, releasing means for each door; hand-operated means for operating said doors; and hand-operated means for operating all of the doors simultaneously through the hand-operated releasing means.

6. A series of self-closing doors; gravity-latches for normally holding said doors open; pulleys mounted at points convenient to the openings for said doors; a fireproof cord attached to each of said latches and extending over one of said pulleys and to a suitable point; a ball-crank lever suitably mounted near said point and having one arm attached to said cord; a hand-pull secured to the other arm of said ball-crank lever and located within the building; and hand-operated means operative upon said cord.

7. A series of self-closing doors; automatic gravity-latches for normally holding said doors open; pulleys mounted near said openings; a fireproof cord attached to each of said latches and extending over one of said pulleys; a hand-pull secured to the free end of each of said cords, a sliding member extending alongside said openings from the upper to the lower end of said openings, said member provided with eyes adapted when said member is lowered to engage protruberances on said cords; and a wire having a weight at one end and extending horizontally across said openings and having its upper end connected to said sliding member and adapted normally to hold said sliding member in its highest position, said wire having tubular links in its horizontal portion.

8. A series of self-closing doors; automatic gravity-latches for normally holding said doors open; pulleys mounted near said openings; a fireproof cord attached to each of said latches and extending over one of said pulleys; a hand-pull secured to each cord; a fireproof cord secured to each door and extending over another of said pulleys and having its end secured to a counterweight; a sliding member extending alongside said openings from the upper to the lower end thereof, said member provided with eyes adapted when said member is lowered to engage the hand-pull cords; and a wire having a weight at one end and extending horizontally across said openings and having its upper end connected to said sliding member and adapted to hold said sliding member in its highest position, said wire having tubular links in its horizontal portion.

9. The combination with a shaft, of ways alongside the openings into said shaft; doors sliding in said ways and effective to close by their own gravity; means for normally holding each of said doors open; hand-operated means for separately releasing each of said holding means; and hand-operated means for simultaneously releasing all of said holding means.

10. The combination with a shaft, of ways alongside the openings in said shaft; doors sliding in said ways; means for normally holding said doors open; hand-operated means for releasing each of said holding means; hand-operated means for simultaneously releasing all of said holding means; and hand-operated means for releasing said doors through the hand-operated releasing means.

11. The combination with a shaft, of fireproof ways alongside said openings into said shaft; fireproof doors sliding in said ways and adapted when closed to overlap the sides of said openings; fireproof means for normally holding said doors open; hand-operated fireproof means for separately releasing each of said holding means; hand-operated means for releasing all of said holding means at once through said hand-operated releasing means.

locking means; and hand-operated means operative upon said hand-operated means.

12. The combination with a shaft, of frequent ways alongside the openings into said shaft; frequent doors sliding in said ways; frequent means for normally holding said doors open; separate hand-operated means for releasing each of said holding means; and facilities means for operating all of said holding means at once through said releasing means.

13. The combination with a shaft having openings; of frequent ways alongside the openings into said shaft; frequent doors sliding in said ways and adapted when closed to overlap the sides of said openings; frequent latch supporting means near said doors; frequent gravity-latches, pivoted to said supporting means above said doors, for normally holding said doors open; a hand-pull inside the building for releasing each of said latches; frequent connections between each of said latches and its respective hand-pull; and inflexible connections for operating all of the latches through the hand-pull connections thereto simultaneously in one of two.

14. The combination, with a light, air or heat shaft having openings therein, of frequent ways located inside the shaft alongside the openings; frequent doors sliding in the ways and adapted to overlap the openings on all sides when closed; cross-pieces connecting the top and bottom of the ways on opposite sides of the openings and having one of their ends turned back on itself; counterweights connected with the doors; latches for normally holding the doors open; hand-pulls connected with the latches; a member alongside each opening sliding in the eyes formed in the ends of the cross-pieces, said member connected with the hand-pull and adapted to operate the same when lowered all of said members being connected together; and hand-operated means for lowering said sliding members.

15. In combination with a sliding door adapted when released to shift automatically; means adapted to move said door in its normal position; manually-operative means for releasing said moving means to permit the door to shift; and means embodying a plurality of heat-actuated devices for operating said releasing means through the action of any one of said devices.

16. The combination with a series of doors adapted when released to shift automatically; releasing means for each door; hand-operated means for operating said means; and hand-operated means for operating all of the doors simultaneously through the hand-operated releasing means.

698,541. INDEX-CARD FOR DUPLICATE WHIST. CHARLES W. HUNT, Philadelphia, Pa. Filed Apr. 5, 1899. Serial No. 64,628. (No model.)

Claim.—1. A set of colored index-cards for separating the four white-hands of a pack of playing-cards in the game of duplicate whist, comprising an index-card for each player, the faces and backs being so colored that the face of each card has the same color as the back of another whereby the hands of the respective players are indicated for the original play and shifted to the opponents for the duplicate play, substantially as described.

2. In combination a series of sets of colored index-cards for duplicate whist comprising four index-cards for each pack of playing-cards used, with an appropriate character on the face of each index-card to identify the pack to which it belongs and an appropriate character on the face and back of one of the four index-cards of each set to indicate the lead, substantially as described.

698,542. FLOORING FOR BUILDINGS. GEORGE W. BENNETT, Worcester, Mass. Filed Nov. 23, 1899. Serial No. 65,570. (No model.)

Claim.—1. The combination of separated posts or supports, and a flooring consisting of a panel of concrete having metallic network inlaid therein, said metallic network comprising strips of wire network, extending directly from wall to wall, and diagonal strips of wire-network extending from wall to wall at angles with the first-mentioned strips of wire-network.

2. A flooring resting on separated supports, and consisting of con-

crete with metallic network inlaid therein, said metallic network comprising strips of wire network, extending directly from wall to wall, and diagonal strips of wire-network extending from wall to wall at angles with the first-mentioned strips of wire-network.

3. A flooring resting on separated posts, and consisting of metallic network formed by strips of wire-netting laid from post to post to cross each other in web-beam fashion, and concrete inlaid in the metallic network.

4. A flooring resting on separated posts, and consisting of metallic network formed by strips of wire-netting laid from post to post, and on the diagonals of the spaces defined by the posts, and concrete inlaid in the metallic network.

5. A flooring resting on separated supports, consisting of concrete having a metallic network inlaid in the bottom layer thereof, with the body portion of said concrete of lighter material than the bottom layer thereof.

698,543. FLOORING FOR BUILDINGS. GEORGE W. BENNETT, Worcester, Mass. Filed Dec. 23, 1899. Serial No. 65,571. (No model.)

Claim.—1. The combination of walls or other longitudinal supports, and a flooring consisting of a panel of concrete having metallic network inlaid therein, said metallic network comprising strips of wire network, extending directly from wall to wall, and diagonal strips of wire-network extending from wall to wall at angles with the first-mentioned strips of wire-network.

2. The combination of walls or other longitudinal supports, and a flooring consisting of a panel of concrete having a metallic network in-

closed in its bottom layer, said metallic network comprising strips of wire-netting arranged crosswise with respect to each other.

3. The combination of walls or other longitudinal supports, and a flooring consisting of a panel of concrete having a metallic network comprising strips of wire-netting extending directly from wall to wall, and laid side by side substantially into contact with each other, with diagonal or bridging strips of wire-netting crossing the first-mentioned strips of wire network at angles therein, the body portion of said concrete being of lighter material than the bottom layer thereof.

698,544. GRAPPLE. JOHN W. BROWN, Boston, Mass. Filed Sept. 24, 1899. Serial No. 71,599. (No model.)

Claim.—1. A device of the character described comprising a rod having right and left hand screw-threads, one having openings in their edges mounted upon the ends of said rod, chains secured in the openings in said rods, hooks in the free ends of said chains, and means for rotating said rod.

2. The combination with a rod having right and left hand screw-threads and a drum secured centrally thereon, of nuts having openings in their edges mounted upon the ends of said rod, chains secured in the openings of said nuts, hooks at the free ends of said chains, and means for preventing the twisting of said chains.

3. The combination with a rod having right and left hand screw-threads and a drum secured centrally thereon, of nuts having openings in their edges mounted upon the ends of said rod, chains secured in the openings of said nuts, hooks at the free ends of said chains, and means for preventing the twisting of said chains consisting of a short chain having hooks at its ends adapted to engage the hooks and the screw-threads.

698,545. HOISTING. ROBERT CHASE, and BENJAMIN WILSON, New York, N. Y. Filed Dec. 23, 1899. Serial No. 65,572. (No model.)

Claim.—1. A hoist provided with a pulley made up of a number of layers, each layer consisting of a sheet of wire mesh having its open spaces filled with an elastic compound containing finely-divided abrasive material.

2. A hoist provided with a pulley made up of a number of layers, each layer consisting of a sheet of wire mesh having its open spaces filled with an elastic compound containing finely-divided abrasive material, some of the wires of the mesh being arranged perpendicularly to the working surface of the pulley.

698,546. GRAIN-CARRIER. ROBERT H. OVERLY, Summit Station, Ohio. Filed Sept. 20, 1899. Serial No. 71,598. (No model.)

Claim.—In a grain-carrier, the combination with a horizontal carrier-frame, a horizontal carrier-belt mounted upon rollers in said horizontal frame and having transverse carrier-plates, an inclined carrier-frame section extending from said horizontal frame, upper and lower rollers being mounted on rollers therein and carrying transverse carrier-plates, of a guard-strip having one end fixed to the horizontal frame, said strip extending as described over the carrier-plates of the horizontal carrier-frame and between the parallel spaces of the inclined frame, the outer end of said strip being curved over and in close proximity to the lower outer belt-carrying roller of said inclined frame, substantially as specified.

698,547. MAIL-SHEDDING APPARATUS. GEORGE A. OWEN, Springfield, Mass. Original application filed Mar. 23, 1899, Serial No. 705,004. Divided and this application filed Apr. 20, 1900. Serial No. 67,080. (No model.)

Claim.—1. In a mail service in a building, a downwardly-extending mailing-chute and a portable receptacle removably supported thereunder provided with the spring-pawl 63, the clutch-door 77 horizontally movable between the mouth of the chute and the top of the receptacle having the spring 74 applied thereto, and having portions thereof engaged by said pawl in the placing of the receptacle beneath the chute, for the purpose set forth.

2. In combination, the mailing-chute having at its lower end the plate or support 62 provided with the depending opposite edge portion 64, the plate 65 secured against and under said portion 64 and provided with the opening 66 and the grooves 67, 67', and the slot extension 67'',

the chest-door *f* hinged to slide between said parts 68 and 69 provided with the recesses 72, the spring 74, and the portable receptacle and means for removably supporting it under said part 68, said receptacle being provided with the pawls 68 arranged to operate substantially as described.

2. The combination with a mailing-chute, of a portable receptacle, and means on which the latter is removably supported under the chute, said receptacle having in the upper opening thereof the hinged cover *g* provided with tumblers-cochets 80 and spring-pressed tumblers 82 therein, the corresponding series of tumblers-cochets provided in the upper marginal portion of the receptacle having tumblers therein and a tumbler-adjusting device provided on the support for the said receptacle subject in which the locking devices are brought on the replacement of the receptacle under the chute.

4. The combination with the supporting part *c*, of the portable receptacle provided with the tumblers-cochets 77 and the tumblers 78, and provided with the recess 87 and a plunger-like forcing device therein, the hinged cover *g* provided with the tumblers-cochets 80, and the spring-pressed tumblers 82, and having the lower-legs 88 and the stationary part 84 comprising the tumblers-operating words, substantially as described.

5. The combination with a mailing-chute and a receptacle-support thereunder, of the receptacle having the hinged cover and automatic locking and unlatching devices substantially as described, the elevating-spring for the cover and the cover-opening device consisting of the leg 88 on the cover and the double-plungers 86, 86, and intermediate spring 90 in a socket in the marginal portion of the cover, as shown.

6. The combination with a mailing-chute, of a portable receptacle removably supported thereunder, having a discharging-mouth, and a closing-door therefor, locking device between each door and the wall of the receptacle consisting of tumbler-cochets in the door and in the wall adjacent thereto, with slots in said wall leading to said cochets, and an opening-spring for the door.

7. The portable receptacle having the entrance-opening and a discharging-mouth, a cover hinged in the entrance-opening, automatic locking and unlatching means for said cover, the closing-door *A* having tumbler-cochets, the wall of the receptacle adjacent said door also having cochets with openings from without leading thereto, and the spring-pressed tumblers 86, substantially as described.

8. The combination with the chest letter-box having a receiving-opening and a series of projections 80 adjacent thereto, of the portable receptacle having the delivery-mouth provided with a hinged door there-within, and locking device between the door and adjacent receptacle-wall comprising tumblers and cochets therefor in both the wall and door, and apertures leading from the exterior of the receptacle-wall through which said projections 80 may enter, substantially as and for the purpose set forth.

698,548: TRACK-SUPPORTING APPARATUS. GEORGE A. OWEN, Springfield, Mass. Filed June 24, 1901. Serial No. 68,744. (No model.)

Claim.—1. In a track-supporting apparatus, of the character indicated herein, a post having an offset portion 40, and thereabove a post extension, combined with a trackway, having its position adjusted on upper part of the said offset portion 40, whereby the conveyor to run suspended from the trackway may pass unobstructedly through the space while said offset portion of the post, longitudinal flutings support on, leading from post to post, and depending connection between the latter and the track.

2. The post having in the upper extension thereof cheeks 48 mounted to freely turn and provided with legs 46, of the longitudinal cables, and portions of which are passed around the cheeks, and have connections with turnbuckles which are also connected with the said post-legs.

3. The post having in the upper extension portion thereof, recesses 44 and double cheeks mounted and freely rotatable therein, and provided with the legs 46, of the cables 57, the end portions of which are passed around the cheeks in opposite directions, the trackway having supporting-eyes at its top and turnbuckles comprised in depending connections between intermediate parts of the longitudinal cables, and said track-supporting eyes and the turnbuckles 48, 48, having connections with the extremities of the longitudinal cables, and the post-legs 46, 46.

4. The post *A* having the double bands 42, 42, and intermediate offset portion 40, and the upper post extension 45 provided near the upper band 42 with the regularly-extended leg 62, combined with the longitudinal cables supported from the upper portions of the post, and having depending track-supporting connections, and cross-roads confined in, and depending below, the legs 62, and having supporting connection with the track, serving to steady the latter adjacent the post.

5. The trackway of tubular form having an underneath median clew-way, and having a connected top eye, and the post having from their upward extension, the longitudinal cables and the depending track-supporting connections 54, the lower ends of which are connected with each of the eyes at the top of the track.

6. The trackway of tubular form having an underneath median clew-way, and having an embracing clip 56, provided at its top with an eye, of the post having upward post extension, the longitudinal cables and depending track-supporting connections 54, the lower ends of which are connected with each of the eyes provided at the top of the track.

7. Track-suspension-cylinders, and the track constructed as follows: the post *A* having the offset portion 40 and the upward post extension having in its upper extremity the recess 44, therebelow the opposite legs 46, and also the legs 62, the double cheeks 48, 48, in the recess, the longitudinal cable 57, and portions of which are passed around the cheeks, the double rods 47, 47, depending and united by turnbuckles, one of each rod having connection with the end of the cable, and the other having a coupling engagement with a post-leg 46, and the trackway having the clip 56, provided with the eye 58, the depending connections 54 having connections with said eyes, and supported by the longitudinal cables, and immediately provided with turnbuckles, rods 56 having supporting connections with the post-legs 62, and depending therebelow, and having a supporting and steadying connection with the portion of the track adjacent the post, substantially as described.

698,549. GEORGE A. OWEN. HARTMAN, Pat. Aug. 21, 1901. Serial No. 68,745. (No model.)

Claim.—1. In a circular-hitting machine, the combination of the needle-cylinder, the needle, including finishing-needle, the rotatable and oscillatory cam-cylinder, the hitting-arms, including offset-arms, a switch-arm, and means operated by the oscillations of the cam-cylinder for rendering said switch-arm active and inactive at a point or points centrally of the finishing-needle, or substantially as, together with picking mechanism for the finishing-needle, and means for rendering said mechanism idle and active at predetermined intervals.

2. In a circular-hitting machine, the combination of the needle-cylinder, its needle, including finishing-needle, the rotatable and oscillatory cam-cylinder, the hitting-arms, including offset-arms, a switch-arm, and means operated by the oscillations of the cam-cylinder for rendering said switch-arm active and inactive at a point or points centrally of the finishing-needle, or substantially as, together with picking mechanism for the finishing-needle, and means for rendering said mechanism idle and active at predetermined intervals.

3. In a circular-hitting machine, the combination of the needle-cylinder, its needle, including finishing-needle, the rotatable and oscillatory cam-cylinder, the hitting-arms, including offset-arms, a switch-arm, and means operated by the oscillations of the cam-cylinder for rendering said switch-arm active and inactive at a point or points centrally of the finishing-needle, or substantially as.

4. In a circular-hitting machine, the combination of the needle-cylinder, its needle, including finishing-needle, the rotatable and oscillatory cam-cylinder, the hitting-arms, including offset-arms, a switch-arm, and means operated by the oscillations of the cam-cylinder for rendering said switch-arm active and inactive at a point or points centrally of the finishing-needle, or substantially as.

lary cam-cylinder, and the hitting-arms, of a vertically-movable support, a switch-arm thereon, and means for automatically raising and lowering said support to move the switch-arm above and between said hitting-arms at a point or points centrally of the finishing-needle, together with picking mechanism for the finishing-needle, and means for rendering said mechanism idle and active at predetermined intervals.

5. In a circular-hitting machine, the combination with the needle-cylinder, its needle, including finishing-needle, the rotatable and oscillatory cam-cylinder, and the hitting-arms, of a vertically-movable support, a switch-arm thereon, and means for automatically raising and lowering said support to move the switch-arm above and between said hitting-arms at a point or points centrally of the finishing-needle, together with picking mechanism for the finishing-needle, and means for rendering said mechanism idle and active at predetermined intervals.

6. In a circular-hitting machine, the combination with the needle-cylinder, its needle, including finishing-needle, the rotatable and oscillatory cam-cylinder, and the hitting-arms, of a vertically-movable support, a switch-arm thereon, and means for automatically raising and lowering said support to move the switch-arm above and between said hitting-arms at a point or points centrally of the finishing-needle, or substantially as.

7. In a circular-hitting machine, the combination with the needle-cylinder, its needle, including finishing-needle, the rotatable and oscillatory cam-cylinder, and the hitting-arms, of a vertically-movable support, a switch-arm thereon adapted to be set between and above said hitting-arms at a point or points centrally of the finishing-needle, or substantially as, means for normally depressing said support, means for raising the same, a latch device for maintaining said slide elevated, and means for tripping said device to release the slide.

8. In a circular-hitting machine, the combination with the needle-cylinder, its needle, including finishing-needle, the rotatable and oscillatory cam-cylinder, and the hitting-arms, of a vertically-movable support, a switch-arm thereon adapted to be set between and above said hitting-arms at a point or points centrally of the finishing-needle, or substantially as, means for normally depressing said support, a cam movable in proximity to the rotary path of the support, means on the support to engage said cam and effect the elevation of the support, a latch device for maintaining said support elevated, and means for tripping said device to release the support.

9. In a circular-hitting machine, the combination with the cam-cylinder and the hitting-arms, of a vertically-movable slide, a switch-arm thereon movable between or above said hitting-arms as desired, means for normally depressing said slide, a cam-lower movable in proximity to the rotary path of the slide, means on the cam-cylinder for engaging said lower from side to side according to the stroke of said cylinder, means on the slide to engage said cam and effect the elevation of the slide, a latch device for maintaining said slide elevated, and means for tripping said device to release the slide.

10. In a circular-hitting machine, the combination of the needle-cylinder, its needle, including finishing-needle, the rotatable and oscillatory cam-cylinder, the hitting-arms, including offset-arms, a switch-arm, means for automatically rendering said switch-arm active and inactive at a point or points centrally of the finishing-needle, or substantially as, picking mechanism for the finishing-needle, and means for rendering said mechanism idle and active at predetermined intervals.

11. In a circular-hitting machine, the combination with the cam-cylinder and its hitting-arms, including the offset-arms, of a vertically-movable support, a switch-arm thereon, means for maintaining said switch-arm yieldingly in a centrally-depending position.

698,550. GEORGE A. OWEN. HARTMAN, Pat. Aug. 21, 1901. Serial No. 68,746. (No model.)

Claim.—1. A finished stocking the upper part of the leg of which is seamless, while the finished or cuff portion, together with the ankle, heel, foot and toe parts, are formed longitudinally of the stocking, substantially as described.

2. A blank for finished hosiery, comprising a seamless tubular part and a lower flat part, the latter being so shaped that when it is folded and its edges secured or connected, the finished portion of a stocking-leg, together with the ankle, heel, foot and toe portions, will be formed, substantially as described.

698,551. DRAFT-SEWING. BERNARD PATTERSON, Cleveland, Ohio. Filed Jan. 2, 1901. Serial No. 61,819. (No model.)

Claim.—1. In a draft-sewing, the combination of a pair of draft-drawers, a pair of center dills above and secured to said drawers, a filling-drawbar between and secured to said dills, a pair of draft-plates secured to said draft-drawers, means connected with said plates to lead into said dills and filling-drawbar, whereby longitudinal displacement of said plates relatively to said dills and filling-drawbar is prevented, the following-plates, springs, yokes and draw-bar.

2. In a draft-sewing, the combination of a pair of draft-drawers, a pair of center dills above and secured to said drawers, a filling-drawbar between and secured to said dills, a pair of draft-plates secured to said draft-drawers and engaging transversely said dills and filling-drawbar, the following-plates, springs, yokes and draw-bar.

3. In a draft-sewing, the combination of draft-drawers, center-dills, a filling-drawbar between said dills and draft-drawers, said plates provided with means to lead into the draft-drawers, dills and filling-drawbar, whereby longitudinal displacement of said plates is prevented relatively thereto, the following-plates, springs, yokes and draw-bar, substantially as described.

4. In a draft-sewing, the combination of draft-drawers, center-dills, a filling-drawbar between said dills and draft-plates, the latter provided with transverse depressions upon their upper surfaces and lugs located in said depressions, said lugs engaging said dills and filling-drawbar.

5. In a draft-sewing, the combination of draft-drawers, center-dills, a filling-drawbar between said dills, and draft-plates, the latter provided with transverse depressions upon their upper surfaces and lugs located in said depressions, said lugs engaging said draft-drawers, dills and filling-drawbar.

698,551.

2. In a device of the class described, the combination of a plurality of valves, each having a movable valve member, and a diaphragm having all of said valve members mounted on one side thereof, said diaphragm being operated by the pressure of steam from a boiler to control the flow through the valves.

3. In a device of the class described, the combination of a steam-supply pipe, a fuel-supply pipe, a diaphragm, a valve having a valve-seat communicating with the steam-supply pipe and mounted upon one side of the diaphragm, a second valve having a valve-seat communicating with the fuel-supply pipe and mounted upon the same side of the diaphragm and means admitting steam to the opposite side of the diaphragm.

4. In a device of the class described, the combination of a casing having a compartment, a steam-supply pipe, a fuel-supply pipe, a diaphragm secured within the compartment, a valve having a movable member communicating with the fuel-supply pipe and secured to the diaphragm, a second valve having a movable member communicating with the fuel-supply pipe and secured on that side of the diaphragm upon which the steam-supply-valve member is mounted, said movable member of the steam-supply valve being provided with an opening communicating with the other side of the diaphragm to move the valve members simultaneously.

5. In a burner for hydrocarbon liquids, the combination with a compartment of an elastic diaphragm extending through said compartment, a liquid-supply pipe having a valve and a valve-seat, the latter being mounted on said disk, a steam-pipe having a valve and a valve-seat, the latter being mounted on said disk and adapted to admit steam to the space under said disk, valve-stems connected with said valves, and a steam-discharge pipe adapted to receive steam with said fluid, substantially as set forth and described.

6. The combination of a casing, a diaphragm mounted within the casing and adapted to be moved by steam-pressure, and a plurality of valves also mounted within the casing, each valve having a movable member secured to the diaphragm.

7. The combination of a casing, a diaphragm mounted within the casing and adapted to be moved by steam-pressure, a steam-supply valve and a fuel-supply valve both of which are mounted within the casing, and a movable valve-seat for each of said valves, secured to the diaphragm.

698,552. GRID OR BOILER. JAMES I. FRANK, Perth, Western Australia, Australia. Filed Mar. 8, 1929. Serial No. 7,857. (No model.)

Claim.—A boiler comprising a grid having a handle and having extensions from its body to form seats, a receptacle to be placed below the grid and having recesses to receive the said extensions, and having a handle, the two handles being so placed as to be in substantial alignment when the members are assembled, and means for holding the members in their assembled relation.

698,553. INJECTOR-BURNER. WILLIAM FLETCHER WHITTIER, Cal. Filed Dec. 14, 1929. Serial No. 59,597. (No model.)

Claim.—1. In a device of the class described, the combination of a plurality of valves, each having a movable member, and means having all of said valve members mounted on one side thereof, said means being operated by the pressure of steam from a boiler to control the flow through the valves.

698,554. AXLE-GAGE. JAMES A. BURNHAM, Woburn, Ind. Filed Oct. 4, 1929. Serial No. 77,929. (No model.)

Claim.—1. In an axle-gage, the combination, with a tubular bar having a longitudinal slot, a contact-piece at one end, and a bracket at the other end; of a rocking beam pivoted to the said bracket and provided with a forked contact-piece at each end, a graduated plate on the said bar, an indicator-rod pivoted to the said rocking beam and projecting into the said tubular bar, and a pointer secured to the said indicator-rod and slidable over the said graduated plate, substantially as set forth.

2. In an axle-gage, the combination, with a tubular bar having a longitudinal slot, a contact-piece at one end, and a bracket at the other end; of a rocking beam pivoted to the said bracket and provided with a forked contact-piece at each end and an arm which projects upwardly from its outer end, a graduated plate on the said bar, an indicator-rod pivoted to the said arm and projecting into the said tubular bar, and a pointer secured to the said indicator-rod and slidable over the said graduated plate, substantially as set forth.

698,555. GREEN SULFUR DYE AND PROCESS OF MAKING SAME. CHRISTOPHER J. VAN, Zurich, Switzerland, assignor to Anilin-Color and Extract Works, formerly John E. Gutz, Zurich, Switzerland. Filed Feb. 5, 1929. Serial No. 52,712. (Specimens.)

Claim.—1. The production of a new green color dyestuff by making the salt-acid of dimethyl-para-amido-para-xylylenediamine, obtainable from dimethyl-para-amidodiphenylamine and normal acids, with polyacids of alkali in presence of water, substantially as described.

2. As a new article of manufacture the green color dyestuff derived from the salt-acid of dimethyl-para-amido-para-xylylenediamine, which forms a dark powder, soluble in water with a dark-violet color, scarcely soluble in alcohol, insoluble in ether and benzene, the watery solution being precipitated by addition of acids in light brown floccs, which are insoluble in ammonia and in sodium-carbonate solution, soluble in concentrated sulfuric acid with blackish-brown color, turning slowly to a grayish-violet shade—the coloring-matter, dyeing premeditated cotton fast green shades, substantially as described.

698,556. AUTOMATIC RAILWAY-GATE. THOMAS R. BROWN and EDWARD G. BURKMAN, Muskegon, Iowa. Filed Oct. 20, 1901. Serial No. 78,616. (No model.)

Claim.—An automatic gate of the character specified, a suitable frame, a movable gate-section mounted on said frame, in combination with tread-rolls 12 and suitable supporting devices intermediate said tread-plate and gate embodying yokes, supporting said tread-rolls, a pivoted gate-controller, and a gate-controlling lever having pivotal connection with said controller whereby the gate will be depressed when said plate is depressed by the wheels of the moving train, and means to restore the gate to a normally elevated position after the train is past, all combined substantially as specified and for the purpose set forth.

698,557. BALL-BEARING. CHARLES E. BARNES, Chicago, Ill. Filed Sept. 17, 1900. Serial No. 20,377. (No model.)

W. D. G.—57

Claim.—1. The combination in a ball-bearing for axle, of the cup, the ball-ring, the cone, the balls and a loose split ring for holding the balls in the cup when the cup and cone are separated, each ring being located in the axial opening between the cup and cone, substantially as specified.

2. The combination with the balls, cone and cup of a ball-bearing of a ball-ring fast in the cup, and a loose split spring-ring for retaining the balls located inside the balls and in the axial opening between the cup and cone, substantially as specified.

698,558. TRAVELING-CASE. HENRY W. BARNHART, New York, N. Y. Filed May 11, 1901. Serial No. 81,716. (No model.)

Claim.—A traveling-case comprising a body open at the top, a cover hinged thereto and open at the top and at the bottom, clasp at the lower part of said cover, trays cut within the cover upon the said clasp, said trays being open at the top, and sliding lids arranged above the said trays to pull out at opposite sides of the cover, and each of a proper size to close one of the said trays.

698,559. SPEED-VEHICLE. CHARLES BOWLER, Buffalo, N. Y. Filed Sept. 2, 1901. Serial No. 81,717. (No model.)

Claim.—An arched axle for vehicles comprising two members having downwardly-converging ends, each end end being formed with recesses, each recess being relatively wide at the ends of the axle, and tapering to a point a considerable distance above each end, spindle-holders provided with eye portions and radially-extending prongs, each prong being adapted to fit snugly in the said recesses, reinforcing-plans secured to the converging ends of the axle for further strengthening the same, and rivets extending through the reinforcing-plans, the axle members and the radiating prongs for binding all such parts rigidly together, substantially as described.

698,560. DOGS HARNESS. WILLIAM T. BURN, Newark, Ohio. Filed June 7, 1901. Serial No. 68,004. (No model.)

Claim.—In a harness, the combination of a plated nose-band having the terminals reduced and one formed with a loop through which the other is adjustably threaded, the extremity or terminal which is passed through the loop being continued into a halter-cape and parts of the band also continued upwardly to form cheek and crown portions, a connecting device for the nose-band terminals to form an adjustable chin-strap, a separable throat-latch continued into a crown portion which is attached at opposite sides to the crown portion continued from the cheek portions by means of clips, the said double crown-bearing parts being free between

the opposite side attached portion thereof, and a brow-rope secured at opposite sides to the crown portion extended from the throat-latch below the points of attachment of the said latter portion to the crown portion extended upwardly from the nose-band, said brow-rope being passed between the strands of the cheek portions.

698,561. HOOKED-BAND FASTENER. ALVIN B. SHUMAKER, Reading, Pa. Filed Dec. 22, 1901. Serial No. 57,547. (No model.)

Claim.—An article of the class described consisting of a body-plate provided with a series of perforations near its edges, and ears projecting from said plate, said ears being arranged at an angle to and inclined toward each other and provided with apertures, a spring-clip formed of wire bent upon itself, the forward end of said clip being bent slightly upward, and the free ends bent away from each other to form arms, said arms being journaled in the apertures in the ears, and teeth on said arms.

698,562. FOLDING DEVICE. HUGH J. SUMMER, Howton, Iowa. Filed Nov. 15, 1901. Serial No. 58,300. (No model.)

Claim.—1. In a device of the class described, the combination of a base, two pairs of upright guides at the corners of one end of the base and adjustable to and from each other, and a rod capable of passing between the guide-rods of each pair.

2. In a device of the class described, the combination of a base, two plates detachably secured to the corners of one end portion of the base and two upright guides fixed to each plate, and a rod passed between each pair of upright guides and to extend at right angles to the longitudinal axis of the base.

3. In a device of the class described, the combination of a base, two plates detachably and adjustably connected with the corners of one end portion of the base, a pair of upright guides connected with each plate and capable of folding on top of the base to a position resting against the base, a rod to pass between the pairs of guide-rods when they are in their upright position, for the purposes stated.

4. In a device of the class described, the combination of a flat base tapered from a maximum at its front end to a thin edge at its rear end, a handle at the front edge of the base, bolts passed upwardly through the corners of the front end portion of the base, two plates 14 each having a plate 16 hinged thereto, said plates being provided with L-shaped slots as set forth, nuts 15 for the bolts 12, two guide-rods 13 on each of the plates 16, and a rod 20 arranged and combined in the manner set forth and for the purposes stated.

698,563. CULTIVATOR. WILLIAM G. SUTY, Rockwell, Minn. Filed Oct. 14, 1901. Serial No. 71,800. (No model.)

Claim.—1. In a cultivator, the combination of a main frame, a drag-bar capable of a vertical movement only and a stationary loop extending from the main frame, the drag-bar guided in the loop.

2. In a cultivator, the combination of a main frame, a drag-bar, a lifting-lever having a crank portion, a rod having a connection with the drag-bar, the upper end of the rod having a lengthwise slot and a cap embracing the crank portion and adjustably connected with the slotted portion of the rod.

3. In a cultivator, the combination of a main frame, two loops supported by the main frame, a yoke having its horizontal portions guided in the loops and a roller located over each horizontal portion of the yoke.

4. In a cultivator, the combination of a main frame, front drag-bar

capable of a bodily movement transverse of the cultivator, foot-levers for raising the drag-bars and guides for the foot-levers preventing lateral movement of the foot-levers.

698,564. ICE-BOX COVER. THOMAS F. BROWN, New York, N. Y. Filed Sept. 4, 1901. Serial No. 74,370. (No model.)

Claim.—1. The ice-box cover described, comprising a sheet of metal forming the body, a sheet of asbestos on the under face thereof, and a covering sheet of woven fabric applied on the under face of said asbestos sheet, the latter and said fabric held in position by folding the edges of the metal upon them and securely clamping both, all combined substantially as specified.

2. The ice-box cover described, comprising a sheet of metal forming the body, a sheet of asbestos on the under face thereof, and a covering sheet of woven fabric applied on the under face of said asbestos sheet, the latter and said fabric held in position by folding the edges of the metal upon them and securely clamping both, and rivets extending through said fabric, asbestos, and metal to hold said fabric and asbestos sheets closely adjacent to said metal sheet throughout the whole area, all combined substantially as specified.

3. The metal sheet C, asbestos sheet D, and fabric sheet E superposed upon each other, the fold G along the margins of said metal sheet, serving to hold the edges of said asbestos and fabric sheets, and the flange G' formed by bending downward the edges of said metal sheet, all combined and arranged to serve with a bar ice-box, substantially as herein specified.

4. The metal sheet C, asbestos sheet D, and fabric sheet E superposed upon each other, the fold G along the margins of said metal sheet, serving to hold the edges of said asbestos and fabric sheets, the flange G' formed by bending downward the edges of said metal sheet, and the rivets F serving to hold said asbestos and fabric sheets to said metal sheet throughout the whole area, all combined and arranged to serve with a bar ice-box, substantially as herein specified.

698,565. BOTTOM-POURING LADLE. CLIFTON W. SUMMER, Bellevue, Pa., assignor to Pennsylvania Car Wheel Company, Pittsburgh, Pa., a Corporation of Pennsylvania. Filed Mar. 10, 1901. Serial No. 51,818. (No model.)

Claim.—A bottom-pouring ladle, having a plug, a yoke from which it is rigidly suspended, an operating-slide to which the yoke is rigidly

applied, a guideway for said slide having an inwardly-inclined projection arranged above the balls and next the slide, and means to reciprocate the slide, substantially as described.

698,566. SNOW-COMPRESSING MACHINE. EDWARD SHENKOFF, Richmond, Va. Filed Feb. 28, 1901. Serial No. 65,401. (No model.)

Claim.—1. In a snow-compressing machine the combination with a stationary thrust-resisting element, of means for presenting snow in front of the same, mechanism for moving said snow-presenting means across the face of the thrust-resisting element, a plunger, and means for actuating the same to compress the snow against said element, substantially as described.

2. In a snow-compressing machine the combination with a stationary thrust-resisting element, of means for presenting snow in front of the same, a plurality of plungers, and means for actuating the same to compress the snow against said element, substantially as described.

3. In a snow-compressing machine the combination with a stationary thrust-resisting element, of a rotating carrier for presenting snow in front of said element, a series of rotating plungers, and means for actuating the same to compress the snow against said element, substantially as described.

4. In a snow-compressing machine the combination with a thrust-resisting element, of a rotating device provided with chambers for gathering snow and presenting it in front of said element, a series of plungers arranged to work in said chambers, and means for actuating said plungers to compress the snow against said element, substantially as described.

5. In a snow-compressing machine the combination with a thrust-resisting element, of a rotating device provided with chambers for gathering snow and conveying it across the face of said element, a series of plungers arranged to work in said chambers, and means for actuating said plungers to progressively compress the snow against said element in its transit thereover, substantially as described.

6. In a snow-compressing machine the combination with a thrust-resisting element, of a rotating device provided with chambers for gathering and carrying snow across the face of said element, plungers carried by said rotating device and arranged to work in said chambers, and means for actuating said plungers to compress the snow against the face of the thrust-resisting element, substantially as described.

7. In a snow-compressing machine the combination with a frame provided with cam-ribs, and a thrust-resisting element, of a rotating device provided with chambers for gathering snow and carrying it across the face of said element, plungers carried by said rotating device arranged to work in said chambers and having means engaging the cam-ribs whereby said plungers are actuated to compress the snow against the face of the thrust-resisting element, substantially as described.

8. In a snow-compressing machine the combination with a frame provided with cam-ribs, and a thrust-resisting element, of a rotating device provided with peripheral chambers for gathering snow and carrying it across the face of said element, and provided also with radial slots, a series of plungers arranged to work in said chambers, and cross-arms on which said plungers are mounted, said cross-arms engaging the cam-ribs and adapted to move in said slots, substantially as described.

9. In a snow-compressing machine the combination with a frame provided with cam-ribs, and a thrust-resisting element, of a rotating drum-like structure comprising end plates, a series of partitions extending between the said plates and forming a series of peripheral snow gathering and carrying chambers, said plates provided with radial slots, and a series of plungers arranged to work in said peripheral chambers and mounted on cross-arms which engage the cam-ribs, substantially as described.

10. In a snow-compressing machine the combination with thrust-resisting elements, of a rotating carrier mounted between said elements and adapted to convey the snow across the face thereof, of a series of plungers carried by said rotating device, and means for actuating the same to compress the snow, substantially as described.

11. In a snow-compressing machine the combination with thrust-resisting elements, of a rotating device mounted between said elements and provided with snow gathering and carrying chambers, of a series of plungers arranged to work in said chambers, and means for actuating the plungers to compress the snow, substantially as described.

12. The combination with a frame provided with snow guides and levers, of a thrust-resisting element, a rotating snow gathering and carrying device for presenting the snow in front of said element, plungers, and means for actuating said plungers to compress the snow against said element, substantially as described.

13. The combination of snow-compressing mechanism and a snow-disintegrator, substantially as described.

14. The combination with a rotating snow-compressing mechanism, of a rotating snow-disintegrator, substantially as described.

15. The combination with snow-compressing mechanism comprising a thrust-resisting element, a rotating snow-carrying device, and plungers for compressing the snow, of a rotating snow-disintegrator, substantially as described.

16. The combination in a snow-compressing machine of a thrust-resisting element, a rotating device provided with snow gathering and carrying chambers, a series of plungers arranged to work in said chambers, means for actuating said plungers, and a rotating snow-disintegrator, substantially as described.

698,567. IMPLEMENT FOR STRIPPING INSULATION FROM WIRE. CLARENCE C. SMITH, Perth Amboy, N. J. Filed June 22, 1901. Serial No. 65,098. (No model.)

Claim.—1. As an article of manufacture, an implement comprising a pair of opposed jaws having a space between them adapted to receive an insulated wire and provided with a cutting edge adapted to cover insulation from each wire, said implement having an abutment at the inner portion of said space against which the wire may abut, the implement being adapted to push the insulation from the wire when the latter is drawn between the jaws, substantially as described.

2. An implement of the character described, comprising a body having a pair of jaws provided with a space between them, the inner edges of the jaws at said space being beveled on converging lines providing substantially parallel cutting edges on one face of the body, said body having a flat face contiguous to the cutting edges on the side opposite the beveled edges, the cutting edges being adapted to cover insulation when an insulated wire is pushed into said space, and the flat face of the body being adapted to bear against the end of the covered insulation to push the same from the wire when the latter is drawn through said space, substantially as described.

698,568. COLLAPSIBLE BOX. ADOLFUS GRUBER, Vienna, Austria-Hungary. Filed Mar. 29, 1901. Serial No. 65,561. (No model.)

Claim.—1. In a collapsible box, the combination with the side and end walls; of locking-hooks A pivoted to the inner face of said end walls, and metal levers K secured to the like faces of the side walls in position to be engaged by said hooks, the latter and their levers recessed in the end and side walls respectively so as to be flush with their inner faces and so positioned that when the hooks are in engagement with their levers the upper faces of the former will be flush with the like faces of the end and side walls, and a lid having bearing on said cover-

ing said hooks and keepers when applied and fastened to the box, substantially as and for the purpose set forth.

2. In a collapsible box, the combination with the side walls having locking-hooks H' and the end walls having keepers K' engaged by said hooks, of fastening devices for detachably securing the said end walls to the said side walls, for the purpose set forth.

3. In a collapsible box, the combination with the side walls having locking-hooks H' and corner angle-braces i lapping over the ends of said hooks, of the end walls having keepers K' engaged by said hooks, and fastening devices for detachably securing said end walls to said side walls, for the purpose set forth.

4. The combination with a box the end walls of which are provided with the lock-outs P' flush with the upper face of said walls, of the barrel provided with a recess P' and a bearing-plate p' projecting over said recess and provided with a hole for the passage of a seal cord or wire and with a counterbore hole in line with the bore of the aforesaid lock-out for the reception of a fastening-bolt B', and a disk pivoted to said plate and adapted to cover the bolt-head, said disk provided with a finger-notch adapted to be brought into register with said bolt-head and with a hole for the aforesaid seal cord or wire, so located that when the disk is turned to cover the bolt-head the seal-cord hole in said disk will register with the like hole in the aforesaid plate p' over recess P', substantially as and for the purpose set forth.

698,569. GRINDING-CAN. FLAVIN J. SUMNER, Newark, N. J. Filed June 17, 1901. Serial No. 94,881. (No model.)

Claim.—1. In a grinding-can, the combination, with an outer vessel provided with a bottom, of a cup depending from the bottom and provided with a sight-window, a flange suspended from the bottom of the cup, and a cylindrical inner cooling vessel secured to the said bottom over the cup and provided with small holes in its side wall adjacent to the said bottom, substantially as set forth.

2. In a grinding-can, the combination, with an outer vessel provided with a bottom, of a cylindrical cup depending from the bottom and provided with a sight-window, a flange suspended from the bottom of the cup, and a straight cylindrical inner cooling vessel of larger diameter than the said cup, said inner vessel being permanently secured to the said bottom around and over the cup and provided with small holes in its vertical side wall adjacent to the said bottom, substantially as set forth.

698,570. ROLLING-MILL FEED-TABLE. HOWE E. SHAW, Fred dock, Pa. Filed Dec. 2, 1901. Serial No. 94,894. (No model.)

Claim.—1. In rolling-mill feed-tables, a Y-shaped switch, and mechanism for feeding the metal forwardly through one leg of the switch and back through the other leg; substantially as described.

2. A rolling-mill feed-table having a Y-shaped switch, and a deflector arranged to shift the end of the section and cause it to enter the other leg of the Y on its return movement; substantially as described.

3. In rolling-mill feed-tables, a Y-shaped switch, positively-driven

feed-rollers in each leg of the switch, and a deflecting device arranged to shift the end of the section; substantially as described.

4. In rolling-mill feed-tables, a table having positively-driven feed mechanism, a Y-shaped switch between it and two sets of rolls, and a deflector in the rear of the Y-shaped switch; substantially as described.

5. In rolling-mill feed-tables a Y-shaped switch, one leg of which lies in a different plane from that of the other leg; and mechanism for feeding the metal forwardly to one leg of the switch and back through the other leg; substantially as described.

698,571. FASTENING DEVICE. CHARLES E. SMITH, New Britain, Conn., assignor to the North & Judd Manufacturing Company, New Britain, Conn., a Corporation of Connecticut. Filed Feb. 12, 1902. Serial No. 94,712. (No model.)

Claim.—1. In a fastening device in combination, a pair of hook members one of said members providing two oppositely-arranged hooks having free ends and lying in the same plane, the width of the entrance-passages between said hooks being less than the width of the holding-pocket within said hooks, the other member carrying two hooks lying in different planes from the plane of the fastening device and from each other, the said hooks being offset and inclined at an angle to produce an opening-wedge.

2. In a fastening device in combination, a pair of hook members each of said members being provided with a pair of free-ended hooks, each of the hook-bills on one member being located in substantially the same plane relatively to the shank portion thereof, the width of the entrance-passages between said hooks being less than the width of the holding-pocket within said hooks, the other of said members being provided with a pair of hook-bills projecting laterally out of the plane common to the hook-shanks and inclining away from each other to form an opening-wedge to the other member.

3. A fastening device comprising two hook members adapted to connect with each other, one of said members having shanks, tending to spring toward each other, curved outwardly and the ends bent back, the width of the entrance-passages between said hooks being less than the width of the holding-pocket within said hooks, the other of said members having shanks provided with free-ended bills, curved outwardly and the ends bent up and offset from the common plane of said shanks, so as to make it necessary to separate the ends of said first member when disengaging the two.

4. A fastening device comprising a pair of hook members adapted to connect with each other, one of said members having shanks curved outwardly and the ends bent back, the width of the entrance-passages between said hooks being less than the width of the holding-pocket within said hooks, the other of said members having shanks whose ends are bent upwardly and outwardly, the two members being so proportioned that the ends of the first member are caused to be sprung outwardly when drawing the two members together and then will spring back to securely lock the two together, the ends of each pair of hooks being free.

698,572. BRICKLAYER-HOOP HOLDER. WILLIAM F. SMITH, Parsons, Kan. Filed Apr. 12, 1901. Serial No. 94,912. (No model.)

Claim.—An emboldery-hoop holder comprising a clamp for engaging a chair, a table or the like, said clamp having a socket formed in one corner thereof and two notches cut into the opposite respective walls of said socket, a bolt-hole in the bottom of said socket, a bolt extending through said hole, a nut on said bolt, a tubular rod extending through the eye of said bolt and pressed thereby into said notches, a plug mounted in one end of said rod and having a tapered transverse opening through its head, a tapering shank fitting within said opening, and a clamp secured to said shank, substantially as described.

698,572.

698,578. MARINE RAILROAD-CAR TRANSPORT. WILLIAM W. SMITH, Kansas City, Mo. Filed May 10, 1901. Serial No. 98,578. (No model.)

Claim.—1. A sea-going railroad-car transport having curved decks, car-tracks thereon, the outer rails of said tracks being higher than the inner rails, and jack-screw braces for holding the cars stationary and heaving the vessel, substantially as described.

2. In a sea-going railroad-car transport having curved and sloping sides and bottom, and a plurality of decks for cars having inclined car-tracks thereon, the combination of a door at the stern of the vessel, hinged at the middle deck and level therewith when lowered, car-tracks on said door leading to the tracks on the middle deck, elevators for transferring cars from deck to deck, jack-screw braces for holding the cars in position and bracing braces for the frame of the vessel, and bulkheads having doors therein for passage of cars; substantially as described.

3. In a sea-going railroad-car transport, the combination, with two adjacent decks, of a car-track upon the lower deck, adapted to carry cars, a stringer adjacent and parallel to said track, a jack-screw brace 18' secured to said stringer, and a supplemental brace 19' secured to and depending obliquely from the upper deck; said braces forming, with cars, a continuous strut for the decks, substantially as described.

4. In a sea-going railway-car transport, having a plurality of decks, car-tracks secured to said decks, admitting ingress and egress of the cars to and from the transport; and braces forming with the cars, continuous struts for the decks, substantially as described.

698,574. ICE-CREAM FREEZER. WILLIAM A. SMITH, Mayville, Ky., assignor of one-half to George W. Selzer, Mayville, Ky. Filed July 17, 1900. Serial No. 124,000. (No model.)

Claim.—1. In an ice-cream freezer, the combination of a tub or receptacle for containing a freezing mixture, means for containing cream in said tub or receptacle and a fanigater arranged at the lower part of the tub or receptacle and adapted to discharge vapors or fumes to the freezing mixture contained therein, substantially as set forth.

2. In an ice-cream freezer the combination of a tub or receptacle for containing a freezing mixture, a cover-plate arranged over said tub and provided with means for supporting a plurality of molds within the tub, handles upon said molds and an auxiliary cover or shield carried by said cover-plate and arranged to house the upper ends of the molds, substantially as set forth.

3. In an ice-cream freezer the combination of a tub for containing a freezing mixture, a cover-plate arranged over the tub and provided with means for supporting a plurality of molds within the tub and auxiliary cover or shield carried by the cover-plate and arranged to house the upper ends of the molds, said shield having an opening for the removal of the molds and being capable of movement on the cover-plate to bring said opening in position over either of the molds, and means to close said opening in the shield, substantially as set forth.

4. In an ice-cream freezer, the combination of a tub for containing a freezing mixture, a plate arranged across the top of the tub and formed with a central opening affording access to said tub, a plurality of molds carried by the plate in annular series about said central opening and depending within the tub, and a fanigater arranged centrally with respect to said series of molds and near the bottom of the tub and adapted to discharge gas or vapors to the freezing mixture within the tub, substantially as set forth.

5. In an ice-cream freezer the combination of a tub for containing a freezing mixture, a plate arranged across the top of the tub and formed with a central opening affording access to said tub, a plurality of molds carried by said plate in annular series about said central opening and depending within the tub and an auxiliary cover or shield mounted to turn in said plate and arranged to house the upper ends of the molds, said shield having an opening for the removal of the molds, substantially as set forth.

6. In an ice-cream freezer the combination of a tub for containing a freezing mixture, a plate arranged across the top of the tub and formed with a central opening affording access to the tub, a plurality of molds carried by the plate in annular series about said central opening and depending within the tub, a fanigater arranged to supply vapors or fumes to the freezing mixture in the tub, and a cover for the central opening in the plate and provided with a vent for the escape of vapors or fumes from the tub, substantially as set forth.

7. In an ice-cream freezer, the combination of a tub for containing a freezing mixture, a plate arranged across the tub, and a series of molds carried by the plate and depending within said tub, said molds being formed with wedge-shaped lower ends, substantially as set forth.

8. In an ice-cream freezer, the combination of a tub, means for containing cream in the tub, and a fanigater consisting of a shell secured to the bottom of the tub and having vents in its side walls, a removable cover for said shell, and a perforated diaphragm supported within the shell, substantially as set forth.

9. In an ice-cream freezer, the combination of a tub, a cover-plate arranged across the top thereof and formed with a central opening and an upwardly-extending flange surrounding said opening, a series of molds carried by the cover-plate, a handle upon each mold and an auxiliary cover or shield having a marginal depending flange adapted to rest on the cover-plate and also formed with a central opening for the passage of the upwardly-extending flange of the cover-plate, said shield being arranged to house the upper ends of the molds, substantially as set forth.

698,575. ELECTRIC-ARC LAMP. PHILIP H. F. SMITH, Mount Vernon, N. Y., assignor of one-half to Jacob Burden, Mount Vernon, N. Y. Filed June 6, 1901. Serial No. 98,210. (No model.)

Claim.—1. An arc-lamp provided with a cathode, a carrier for carrying the cathode and the case of said cathode, a clutch between the carrier and said cathode, an external dash-pot connected with said carrier

and removable weights for the dash-pot, for increasing or decreasing the resistance of the dash-pot to the movement of the solenoid-core, as set forth.

2. An arc-lamp having a supporting-tube formed with an integral flange, a casing having an inner flange adapted to rest on said tube-flange, to separate the heat-developing part of the lamp from the actuating device for the carbon-feed of the lamp, and legs on said inner flange for engaging said tube-flange, as set forth.

3. An arc-lamp having a supporting-tube provided with top and bottom bearings, and a carrier for the solenoid-core and mounted to slide in said bearings, the upper end of the carrier being reduced to form a pin engaging the upper bearing, the said lower bearing having a flexible lining for engaging the outside of the tubular-carrier, as set forth.

4. An arc-lamp having a central supporting-tube formed with a pocket for the solenoid-magnet, a flange integral with the tube for supporting the casing, and a second integral flange for supporting the lever-carbon holder, as set forth.

5. An arc-lamp having a central supporting-tube formed with a pocket for the solenoid-magnet, a flange integral with the tube for supporting the casing, a second integral flange for supporting the lever-carbon holder, and a bearing on the tube for supporting the resistance-coil, as set forth.

698,576. THILL-COUPLER. GEORGE F. WYATT, Seattle, Wash., assignor of one-half to S. H. Harris, Port Jervis, N. Y. Filed Nov. 22, 1901. Serial No. 55,222. (No model.)

Claim.—1. In a device of the class described, the combination of an axle-clip having an upright leg, tapering toward its top, the coupling-iron provided at its back with a tapered recess and having the side walls thereof ground to receive the leg, whereby the latter is wedged in the coupling-iron, means carried by the coupling-iron for engaging the bottom of the leg, and a third-iron pivotally connected with the coupling-iron, substantially as described.

2. In a device of the class described, the combination of an axle-clip having an upright leg, a coupling-iron provided with a recess extending upward from its bottom and receiving the leg, said coupling-iron being provided with ears, a third-iron pivotally mounted between the ears, and the combined actuator and locking spring composed of sides or arms interposed between the third-iron and the coupling-iron, and a depending stem forming a handle and provided with a rearwardly-extending loop engaging the bottom of the leg, substantially as described.

698,577. HORN-DETACHER. EDWARD S. STARR, Milwaukee, Wis. Filed Apr. 12, 1901. Serial No. 55,795. (No model.)

Claim.—1. A horn-detacher comprising a sleeve formed in sections adapted to embrace a thill, a hitch-plate having means whereby it is connected to the harness, a hinge-pin connecting the inner sides of the sections together and to the hitch-plate, a keeper-pin connecting the outer sides of the sections together, and means for withdrawing the keeper-pin.

2. A horn-detacher comprising a sleeve formed in sections adapted to embrace a thill, a hitch-plate having means whereby it is connected to the harness and provided with parallel ears projecting toward the sleeve, a hinge-pin extending through the ears and connecting the inner sides of the sections together, a keeper-pin connecting the outer sides of the sections together, and means for withdrawing the keeper-pin.

3. A horn-detacher comprising a sleeve formed in sections adapted to embrace a thill, a hitch-plate formed with top and bottom loops for the reception of the hook-head, and girth-staps respectively, and with parallel ears projecting toward the sleeve, a hinge-pin extending through the ears and connecting the inner sides of the sections together, a keeper-pin connecting the outer sides of the sections together, and means for withdrawing the keeper-pin.

4. A horn-detacher comprising a sleeve adapted to embrace a thill, a hitch-plate hinged to the sleeve, and having means whereby it is connected to the harness, and a spring-controlled loop adapted to slide on the hitch-plate, and adapted to be connected with the breast-stap.

5. A horn-detacher comprising a sleeve adapted to embrace a thill, a hitch-plate hinged to the sleeve, and provided with ears having notches, a slide-loop having its side bars in engagement with the notched ears, and adapted to be connected to the breast-stap, and a cushioning-spring interposed between one end of the slide-loop and the hitch-plate.

6. A horn-detacher comprising a sleeve adapted to embrace a thill, a hitch-plate having means whereby it is connected to the harness, a slide-loop having ears and mounted on the hitch-plate and having means whereby it is connected with the breast-stap, a hinge-pin passed through the ears of the slide-loop and connecting the hitch-plate with the sleeve, a cushioning-spring extending the hinge-pin and interposed between the ears and the hitch-plate and a detachable keeper-pin.

698,578. HALL-CURLER. HERMAN R. H. SWINER and DANIEL J. L. SWINER, Red Bank, Pa. Filed Apr. 27, 1902. Serial No. 57,735. (No model.)

Claim.—1. A hall-curler comprising a knob, having one or more rods attached thereto and a spring member attached to said knob, arranged substantially parallel to the rod or rods said spring member being adapted to fit over the top edge of a lamp-chimney and hold the rod adjacent to the flame, substantially as shown and described.

2. A hall-curler comprising a knob having an annular shoulder attached at one point, a rod or rods attached to the knob, and a spring member attached to the knob, above the shoulder, said member resting in the notch projecting below the knob, and resting substantially parallel to the rod or rods, for the purpose described.

698,579. FILLING-REPLENISHING LOOM. WALLACE I. STEPHENS, Milford, Mass., assignor to Draper Company, Hopedale, Mass., a Corporation of Maine. Filed Nov. 29, 1901. Serial No. 54,945. (No model.)

Claim.—1. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, a feeder to intermittently engage the filling in the shuttle, and an actuating device, governed by or through the feeder, to actuate said controlling means, presence of filling in the shuttle acting through the feeder to prevent, and predetermined exhaustion of the filling permitting, movement of the actuating device by the filling-carrier to actuate the controlling means.

2. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, a feeder to intermittently engage the filling in the shuttle, and an actuating device for said controlling means, carried by and normally movable with the feeder, presence of filling in the shuttle acting to move the feeder and actuating device in unison, and predetermined exhaustion of the filling effecting movement of the actuating device by the filling-carrier to thereby actuate the controlling means.

3. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, a feeder to intermittently engage the filling in the shuttle, and an actuating device for said means, carried by and limitedly movable relatively to the feeder, presence of filling in the shuttle preventing, and predetermined exhaustion of the filling effecting, initial movement of the actuating device by the filling-carrier to thereby actuate the controlling means.

4. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, a yieldingly-contained feeder to engage and to intermittently engage the filling in the shuttle, and an actuating device for said controlling means, carried by and limitedly movable relatively to the feeder, presence of filling in the shuttle effecting simultaneous movement, and predetermined exhaustion of filling effecting relative movement of said feeder and actuating device by the filling-carrier, to thereby actuate the controlling means.

5. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, a yieldingly-contained feeder having a bifurcated end to intermittently engage the filling in the shuttle, and an actuating device for said controlling means, carried by and relatively movable on the feeder, and having a filling-engaging member between the parts of the bifurcated end of the feeder, presence of filling in the shuttle preventing, and predetermined exhaustion of the filling permitting, movement of the actuating device by or through the filling-carrier relatively to the feeder, to thereby effect the operation of the controlling means.

6. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor including a detent, a feeder to intermittently engage the filling in the shuttle, and an actuating device governed by or through the feeder, to operate the detent, presence of filling in the shuttle acting through the feeder to prevent, and predetermined exhaustion of the filling permitting, initial movement of the actuating device by the filling-carrier, to thereby operate the detent.

7. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, including a detent, a yieldingly-contained feeder, to intermittently engage the filling in the shuttle, and an actuating device for the detent, mounted on and limitedly movable relatively to the feeder, presence of filling in the shuttle acting through the feeder to prevent, and predetermined exhaustion of the filling permitting, movement of the actuating device by or through the filling-carrier relatively to the feeder, to thereby operate the detent.

8. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, an actuating device for said means, mounted on and movable relatively to the feeder, and a feeder to cooperate with the filling in the shuttle and maintain the actuating device inoperative until predetermined exhaustion of the filling, the actuating device at such time being moved by or through the filling-carrier relatively to the feeder into position to effect the actuation of the controlling means.

9. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, a feeder yieldingly contained in position to intermittently engage and to be moved by the filling in the shuttle until exhaustion thereof to a predetermined extent, and a normally inoperative actuating device for said means, slightly mounted on the feeder and movable by or through the filling-carrier into position to effect the actuation of the controlling means, upon predetermined filling exhaustion.

10. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, a feeder to intermittently cooperate with the filling in the shuttle until predetermined exhaustion of the filling, and an actuating device movable mounted on the feeder to engage and transmit the movement of the filling-carrier primarily to said controlling means, by or through movement of the actuating device relatively to the feeder, to effect actuation of the controlling means upon predetermined filling exhaustion.

11. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor including a detent, a yieldingly-contained feeder to intermittently engage the filling in the shuttle, an actuating device mounted on and longitudinally movable relatively to the feeder, said device including a spring-operated stud, and means to normally maintain it inoperative, presence of filling in the shuttle preventing release of the stud, and predetermined exhaustion of the filling acting by or through the filling-carrier to operate the stud and effect the actuation of the controlling means.

12. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, a longitudinally-movable, yieldingly-contained feeder movable on alternate pins by and until predetermined exhaustion of the filling in the shuttle, and an actuating device for said means, movable with and also relatively to the feeder, the feeder and said device moving in unison until predetermined exhaustion of the filling permits movement of the actuating device relatively to the feeder, by or through the filling-carrier, to effect actuation of the controlling means.

13. In a loom, a shuttle adapted to contain a filling-carrier, filling-replenishing mechanism, controlling means therefor, including a detent and a latch normally maintained inoperative thereby, a yieldingly-contained feeder to engage and to be moved by the filling in the shuttle on alternate pins, until predetermined filling exhaustion, and an actuating device slightly mounted on the feeder and having a spring-controlled stud normally out of the path of the detent, movement of the actuating device by the filling-carrier relatively to the feeder upon predetermined exhaustion of the filling releasing the stud to enter the path of the detent and to thereafter move the detent to release the latch.

14. In a loom provided with filling-replenishing mechanism, controlling means therefor, a shuttle adapted to contain a filling-carrier and having a slot in its side wall, a yieldingly-contained feeder, and an actuating device mounted on and movable relatively to the feeder, the feeder and the inner end of said device intermittently entering the slot to engage the filling in the shuttle, to be moved in unison thereby until predetermined filling exhaustion, predetermined exhaustion of the filling permitting movement of the actuating device relatively to the feeder, by or through the filling-carrier, to thereby render said device operative to effect the actuation of the controlling means.

15. In a loom provided with filling-replenishing mechanism, controlling means therefor, a shuttle having a slotted side wall and adapted to contain a filling-carrier having an annular enlargement on its barrel, a yieldingly-contained, longitudinally-movable feeder adapted to enter the slot and engage the filling at one side of said annular enlargement, and an actuating device mounted on and movable longitudinally upon the feeder, said device comprising an actuator extended rearwardly adjacent the inner end of the feeder, to enter the slot in the shuttle, a spring-controlled stud on the feeder and extended through an elongated slot in the outer end of the said actuator, and a latch on said stud, normally engaged by the actuator to maintain the stud inoperative, exhaustion of the filling to cause the annular enlargement and pivot movement thereby of the actuator relatively to the feeder releasing the latch of the stud, the latter moving into operative position to thereafter effect the actuation of the controlling means.

16. In a loom provided with filling-replenishing mechanism, controlling means therefor, a shuttle having a slotted side wall and adapted to contain a filling-carrier having an annular enlargement on its barrel, a bifurcated feeder having a tubular body, an actuator extended between the bifurcated portions of the feeder and slightly supported in the tubular body thereof, a spring-controlled stud transversely movable in said body and extended through an elongated slot in the said annular enlargement, a latch on the stud, to normally engage a part of and to be maintained inoperative by said actuator, the latter having a releasing-notch adjacent the latch, a fixed support for and in which the feeder is longitudinally movable, said support

part having a slot therein for the steel, a controlling-spring for the steel, and a device on said support to return the steel to its operative position, pressure of filling in the elastic preventing, and predetermined exhaustion of the filling preventing, relative movement of the steel and actuator, in thereby release the steel and operatively position the same and to thereafter effect the operation of the controlling means by longitudinal movement of the operatively-positioned steel in the dotted support.

17. In a feeder-loom, a tubular support having a longitudinal slot, a feeder longitudinally movable in said support, a feeder-spring, an actuator mounted on and slidable in the feeder and having a transverse, elongated, upright slot and a notch at the lower end thereof, a steel mounted in the feeder and extended through the slot in the actuator, a spring to lift the steel and bring its upper end above the top of the longitudinally-slotted support, a latch on the lower end of the steel, and a spring between the actuator and feeder, tending to move them oppositely, the latch normally engaging a portion of the actuator adjacent the notch therein, movement of the actuator relatively to the feeder acting to release the steel, combined with filling-replenishing mechanism, and controlling means therefor, actuated by movement of the released steel in the longitudinal slot of the support.

18. In a loom, a shuttle adapted to contain a filling-carrier having an annular enlargement on its barrel, filling-replenishing mechanism, controlling means therefor, including a device, an actuating device to operate the latter, and a feeder; the feeder and actuating device being arranged to cooperate with the filling in the shuttle and to simultaneously moved thereby until exhaustion of the filling to an extent sufficient to permit engagement and movement of the actuating device by said annular enlargement prior to filling-induced movement of the feeder, to thereby actuate the controlling means.

698,580. STUDENT'S LAMP. ARNOLD P. STUBBS, Oswego, N. Y. Filed Jan. 16, 1900. Serial No. 1,891. (No model.)

Claim.—1. The combination with a central-draft burner, of a contracting-ring supported above the wick thereof, and a main chimney supported above the wick and with its lower end surrounding the contracting-ring, substantially as set forth.

2. The combination with a central-draft burner, of a series of supporting-legs maintained by said burner, a contracting-ring carried by said supporting-legs above the wick, and a main chimney carried by said supporting-legs above the wick with its lower end surrounding said contracting-ring, substantially as set forth.

3. The combination with a central-draft burner, of a series of supporting-legs carried by said burner, shoulders formed on said legs, a contracting-ring carried by said legs above the wick, and a main chimney supported by said shoulders above the wick with its lower end surrounding said contracting-ring, substantially as set forth.

4. The combination with a central-draft burner, of a plurality of supporting-legs carried by said burner, an elastic ring carried by said legs and engaging the outside of the burner, a contracting-ring carried by said legs and located above the wick, and a main chimney carried by said legs above the wick with its lower end surrounding said contracting-ring, substantially as set forth.

5. The combination with a central-draft burner, of a series of supporting-legs carried by said burner, a contracting-ring carried by said legs above the wick, a main chimney carried by said legs above the wick with its lower end surrounding said contracting-ring, and elastic extensions of said legs engaging the interior of said chimney, substantially as set forth.

698,581. ROAD-GRADER. BERNARD SCHMIDT, Ontario, Canada. Filed Dec. 18, 1901. Serial No. 86,003. (No model.)

Claim.—1. In a road-grader, the combination of a scraper adapted to be arranged diagonally across the line of a running-gear, a post attached to each end of the scraper, means for connecting one post to a running-gear, an adjusting-lever and means for connecting the other post to said running-gear, the said draft-chain attached to one post, a side draft-chain attached to the other post, and a cross draft-chain, substantially as described.

2. In a road-grader, the combination of a scraper adapted to be arranged diagonally across the line of the vehicle, a short metallic bar secured to the scraper near one end, a slotted and web-formed post fastened to said bar, a keeper in which said slotted post is slidably confined, a pivot arranged to engage with the web on said post, and a lever connected with said post and supported by an independent fulcrum-post, substantially as described.

3. In a road-grader, the combination of a scraper adapted to be arranged diagonally across the line of a running-gear, a post attached to the scraper near one end and provided with a rack, another post attached to the scraper near its other end, keepers adapted to be secured to the running-gear and loosely receiving said posts, means for adjustably fastening one of the keepers and one of the posts together, a pivot arranged to engage with the rack on the other post, a lever connected to the last-named post, a main draft-chain connected to the forward end of the scraper, a side draft-chain connected to the rear portion of the scraper, and a cross draft-chain attached to the scraper and to suitable means whereby it may be connected with the running-gear, substantially as described.

698,582. PROPELLER-WHEEL. EDWARD K. STUBBS, West Superior, Wis. Filed Dec. 18, 1901. Serial No. 86,770. (No model.)

Claim.—1. A propeller-wheel, comprising a hub, blades radiating therefrom and each set upon an angle with relation to the longitudinal axis of the hub, each of the blades gradually increasing in width from its line of juncture with said hub for a comparatively short distance, and

from thence to the outer end being substantially of uniform width and curving laterally rearwardly and having its front face convex, the rear face of the blade being substantially flat, and the blade being comparatively thick near its base and tapering to its outer end, substantially as described.

2. A propeller-wheel, comprising a hub, blades radiating therefrom and set upon an angle with relation to the longitudinal axis of the hub, each of the blades gradually increasing in width from its line of juncture with said hub for a comparatively short distance, and from thence to the outer end being substantially of uniform width and curving laterally rearwardly and having its front face convex as to its thickness, width and length, the rear face of the blade being substantially flat as to its thickness and width, and the blade being comparatively thick near its base and tapering on its forward face to its outer end, substantially as described.

3. A propeller-wheel, comprising a suitable hub, blades radiating therefrom and disposed at an angle to the radial axis of the hub, the edges of each blade curving outwardly from their juncture with the hub to a suitable distance, and thence extending in a substantially straight line to its outer end, all the blades being disposed slightly rearwardly, and a laterally-extending flange carried at the outer end of each of said blades, and extending transversely for the full width thereof, each of said flanges having its outer face rounded and its under face beveled so as to produce a comparatively sharp edge approximately continuous with the edges of the respective blades, substantially as described.

4. A propeller-wheel comprising a hub and blades radiating therefrom, each of which blades is set at a non-spiral angle to the longitudinal axis of said hub, each of which blades has a broad and thick junction with said hub, diminishing in thickness from the center of the blade at the hub toward its edges, each of said blades being bent rearwardly and uniformly throughout its width at a transverse line drawn at any desired distance intermediate the hub and the end of the blade, each blade being provided with a terminal flange extending rearwardly at its outer end, each of said blades increasing in width from its junction with said hub to a transverse line at a suitable distance from said hub, thence maintaining a uniform width to the outer extremity of the blade, substantially as described.

698,583. PRINTING DEVICE. EDWARD K. STUBBS and FRANK A. HAY, Columbus, Ohio. Filed Feb. 4, 1901. Serial No. 86,800. (No model.)

Claim.—In a printing device, the combination with a frame or frame 1, clamping-bars or followers 2 arranged to slide between the side arms of said frame and end-arms curving in rounded openings in the end of the frame, of type-clamping bars arranged in pairs between said followers, each pair comprising adjustably-connected bars 3 and 4 and angular type-bodies adapted to have their vertical ends clamped between said bars and their upper horizontal ends bearing on said bars 3, substantially as specified.

698,584. CURVE-PROPELLER. EDWARD K. STUBBS, West Bay City, Mich. Filed Jan. 23, 1902. Serial No. 89,110. (No model.)

Claim.—A propeller for vessels comprising in combination a series of helical blades of greater length than the diameter of the propeller; a hub integral with said blades; an axial hole through said hub, the outer portion of the length of said hole being adapted to fit the propeller-shaft; the remaining portion of said hole being enlarged from the middle of the hub toward its forward end, to form a conical recess; openings through the conical shell of the hub; and cramping-bars across said openings; together with a conical rearwardly-extending bearing secured to the vessel and fitting the conical recess of the hub, said bearing having an axial shaft-opening, all arranged substantially as and for the purposes set forth.

698,585. RUB AND AXLE BEARING. ANDREW J. TINKER, Cincinnati, Ohio. Filed Dec. 9, 1901. Serial No. 86,100. (No model.)

Claim.—1. In a hub and axle bearing, the combination of a non-rotary axle-journal, a rotary hub fitted thereto with its bore enlarged at its inner end to form a recess between axle and hub, a washer occupying this recess, being at the same time with its inner side in contact with the axle which it surrounds, a band having a tendency to contract surrounding this washer which later is provided with a cut disposed in a manner to permit it to yield to the pressure imparted by such contraction and means to hold this washer to the hub so as to cause the same to rotate therewith.

2. In a hub and axle bearing, the combination of a non-rotary axle-journal, a rotary hub fitted thereto with its bore enlarged at its inner end to form a recess between axle and hub, a washer occupying this recess, being at the same time with its inner side in contact with the axle which it surrounds, a band having a tendency to contract surrounding this washer which later is provided with a cut disposed in a manner to permit it to yield to the pressure imparted by such contraction and an annular plate to close the recess at the inner end of the hub to confine the washer therein.

3. In a hub and axle bearing, the combination of a hub having the bore of the hub, the same being enlarged at one end to form a recess, a washer surrounding the axle, an elastic ring surrounding this washer, both occupying the recess mentioned, both being open with a space between their separated ends to permit contraction, a pin 23 projecting into the recess of the hub engaging an opening in the washer to cause the same to rotate with the hub and an annular plate 26 affixed to the edge of the enlarged part of the hub to close the recess therein.

4. In a hub and axle bearing, the combination of a rotary hub having its bearing at its outer end and a recess at its inner end, a non-rotary axle having an enlargement at the inner end of the journal thereof and within the recess of the hub, an open washer mounted on this enlarged part of the axle and a ring having contracting properties surrounding this washer and both occupying the recess at the inner end of the hub.

5. In a hub and axle bearing, the combination of a non-rotary axle-journal, a rotary hub fitted thereto with its bore enlarged at its inner end to form a recess between axle and hub, a washer occupying this recess, being at the same time with its inner side in contact with the axle which it surrounds, a band having a tendency to contract surrounding this washer which later is provided with a cut disposed in a manner to permit it to yield to the pressure imparted by such contraction and packing of yielding material between the washer and the band to prevent escape of lubricant through the open end of the washer.

6. In a hub and axle bearing, the combination of a non-rotary axle-

Journal, a rotary hub fitted thereto with its bore enlarged at its inner end to form thereat a recess between axle and hub, a washer occupying this recess, being at the same time with its inner side in contact with the axle which it surrounds thereat, a band having a tendency to contract surrounding this washer, which latter is provided with a cut disposed in a manner to permit it to yield to the pressure imparted by such contraction and packing in the cut of the washer to prevent escape of lubricant there-through.

698,586. CULTIVATOR AND WHEED-CUTTER. JOHN H. FUGER, JR., Lima, Cal. Filed Jan. 22, 1902. Serial No. 91,548. (No model.)

Claim.—1. In a machine of the class described, the combination of a beam, blades secured to the beam each blade having a flat outer portion, arms extending from the outer portion and secured to the beam, and brace-arms for the blades.

2. In a machine of the class described, the combination of a beam, U-shaped blades secured to the beam each having a flat outer portion, and brace-arms adjustably connecting the blades to the frame whereby the outer portions may assume various degrees of inclination.

3. In a machine of the class described, the combination of a forward beam, a rear beam secured to the forward beam by bars, U-shaped blades depending from the rear beam, opening-closures on the beams securing the bars and blades in position, and on the threaded ends of the beams, and brace-arms adjustably connecting the blades to the bars.

4. In a machine of the class described, the combination of a beam, blades secured thereto, each consisting of a flat outer portion beveled at its upper side to provide a cutting edge, and arms extending from the ends of the outer portion said arms being beveled at their lower ends and provided at their upper ends with means for connection with the beam.

698,587. PRINTING-BLOCK FOR OIL-CLOTH-PRINTING MACHINE. EDWARD F. TETTER, Camden, N. J. Filed May 20, 1901. Serial No. 68,199. (No model.)

Claim.—1. In a printing-block, a metallic pen-shaped framework, longitudinally-inclined ribs formed with said framework and upon the interior of the same, plastic substance filling the interior of the framework, said plastic substance adapted to harden and to hold in the framework by the inclined ribs, and means for securing the printing-block to the framework of the press, substantially as described and for the purpose specified.

2. In combination with a printing-block consisting of a metallic framework, vertical side walls formed with said framework, inclined end walls formed with said framework, a bottom to which the side walls are secured said bottom and walls forming a pen-shaped receptacle, a plastic substance filling the receptacle formed by the pen-shaped framework, said plastic substance adapted to harden, means arranged upon the interior of the framework to retain the hardened substance in position, and means for securing the block to the supporting framework, substantially as described and for the purpose specified.

3. In combination with a printing-block of the character described, longitudinal ribs formed upon the back of the block, holes formed through said ribs, screw-ends, heads formed upon the lower ends of said screw-ends and adapted to pass through the holes in the ribs, yokes through which the upper ends of the screw-ends are adapted to pass, the ends of said yokes adapted to rest upon the upper surface of the frame of the machine, said frame being adapted to the ribs upon the printing-block against the under surface of the frame, substantially as described.

698,588. SKEWED-BELDER. JAMES ULL, Wisconsin Veteran Home, Wis. Filed Jan. 7, 1901. Renewed Mar. 27, 1902. Serial No. 101,324. (No model.)

Claim.—A skewed-belder, formed from a single length of spring-wire, which is folded intermediate of its ends into substantially U shape, the bend being bent back to lie in a plane at one side of the plane of the opposite intermediate side portion of the wire and form a button-embroidering loop, the opposite ends of the wire being bent back upon the same side with the loop, lying at opposite sides of the closed portion thereof, and forming collar-engaging springs located between the planes of the loop and the intermediate side portions of the wire, and a body-plate lying between the intermediate side portions of the wire, and having its opposite ends folded upon said intermediate wire portions, and provided with intermediate means for connection with a needle.

698,589. SELF-CLOSING WINDOW. BENJAMIN VAN BORDEN and HENRY C. SMITH, Boston, Mass. Filed Jan. 12, 1902. Serial No. 1,261. (No model.)

Claim.—1. The combination of a window-casing, a window-cash movable in said casing, its balancing-weight, an auxiliary weight and a bracket supporting the auxiliary weight, detachably held at one end to a support and detachably secured at its other end by flexible sides, which weight upon the release of the bracket is adapted to compensate with the balancing weight or weights of the cash in overbalance it or them and cause it or them to close the cash and hold the cash closed.

2. The combination of a window-casing, its balancing-weight, an auxiliary weight, and a bracket in the weight-pocket supporting the auxiliary weight, adapted to become released by means here and provided with means for engaging, when released, the cord or chain of a balancing-weight, as and for the purpose set forth.

3. The combination of the window-casing, the window, its balancing-weight contained in the pocket of the window-casing, an auxiliary weight in a pocket of the casing, and a bracket supporting the auxiliary weight, detachably held in the pocket by means extending without the pocket and there detachably held by flexible sides, as and for the purpose set forth.

4. The combination of a window-casing, a lower cash and an upper cash movable therein, balancing-weights contained in the pockets of the casing, cords or chains connecting said weights with the lower window-cash, means for releasing in case of undue heat in the vicinity of the cash one or more of said weights from said lower window-cash, whereby the window-cash may then overbalance the remaining weight or weights and, if raised, close automatically, balancing-weights contained in the pockets of the casing, cords or chains connecting said weights with the upper win-

low-cash and an auxiliary weight or weights normally inactive, and detachably held by means detachable by means here, which weight or weights, when released, combine with the weights of the upper cash and serve with them to close said cash, if open, and to hold it closed.

698,590. CASTING-MACHINE. CURTIS H. VERNER, Hartford, Conn. Filed Nov. 27, 1900. Serial No. 758,202. (No model.)

Claim.—1. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric, of an outlet-nozzle through which molten metal is discharged; a shiftable mold; means for advancing the mold to a position when a casting is to be made in which it contacts with the nozzle and for withdrawing it therefrom; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting the space extending from the valve to the bottom of the mold-space proper and through and into which the molten metal passes during its flow; a power-driven device in the machine; and means operatively connected with said device for actuating said valve to first admit molten metal under pressure to the exhausted mold, and then to shut off all communication of the metal therewith.

2. In a casting-machine, the combination with a plunger for subjecting a mass of molten metal to pressure, of an outlet-nozzle through which molten metal is discharged; a shiftable mold; means for advancing the mold to its casting position and for withdrawing it therefrom; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting the space extending from the valve to the bottom of the mold-space proper, and through and into which the molten metal passes during its flow; a power-driven device in the machine; and means operatively connected with said device for actuating said valve, and immediately afterward actuating the plunger, and then closing the valve after the mold has been filled.

3. In a casting-machine, the combination with a melting-tank and a plunger, of an outlet-nozzle through which molten metal is discharged; a shiftable mold; means for advancing the mold to its casting position and for withdrawing it therefrom; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting the space extending from the valve to the bottom of the mold-space proper and through and into which the molten metal passes during its flow; a shaft; means on said shaft, one for holding the plunger in an inoperative position, and another for opening said valve; and springs for effecting the operation of the plunger and the valve when released from their respective means.

4. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric, of an outlet-nozzle through which molten metal is discharged; a shiftable mold; a vacuum-chamber in which the mold is located; means for advancing the mold to a position when a casting is to be made in which it contacts with the nozzle and for withdrawing it therefrom; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting the space extending from the valve to the bottom of the mold-space proper, and through and into which the molten metal passes during its flow; a power-driven device in the machine; and means operatively connected with said device for actuating said valve to first admit molten metal under pressure to the exhausted mold, and then to shut off all communication of the metal therewith.

5. In a casting-machine, the combination with means for subjecting a mass of molten metal to pressure greater than atmospheric, of a shiftable mold; a vacuum-chamber in which the mold is located; a stuffing-box in a wall of the vacuum-chamber; a mold-extender extending through the stuffing-box; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting the vacuum-chamber, and thereby exhausting the space extending from the valve to the bottom of the mold-space proper; a power-driven device in the machine; and means operatively connected with said device for actuating said valve to first admit molten metal under pressure to the exhausted mold, and then to shut off all communication of the metal therewith.

6. In a casting-machine, the combination with means for subjecting a mass of molten metal to pressure greater than atmospheric, of a shiftable mold; a vacuum-chamber in which the mold is located; a stuffing-box in a wall of the vacuum-chamber; a mold-extender extending through the stuffing-box; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting the vacuum-chamber, and thereby exhausting the space extending from the valve to the bottom of the mold-space proper; a power-driven device in the machine; and means operatively connected with said device for actuating said valve to first admit molten metal under pressure to the exhausted mold, and then to shut off all communication of the metal therewith.

7. In a casting-machine, the combination with a melting-tank and an outlet-nozzle through which molten metal is discharged, of a well communicating with the melting-tank; a plunger for subjecting molten metal therein to pressure; a valve device embodying a pair of valve parts for simultaneously closing communication between the well and the melting-tank, and opening the passage through the nozzle and vice versa; a shiftable mold; means for advancing the mold to its casting position and for withdrawing it therefrom; means for exhausting the space extending from the valve part controlling the passage through the nozzle, to the bottom of the mold-space; a power-driven device in the machine; and means operatively connected with said device for actuating the plunger and the valve device in proper order.

8. In a casting-machine, the combination with a melting-tank and an outlet-nozzle through which molten metal is discharged, of a well communicating with the melting-tank; a plunger for subjecting molten metal therein to pressure; a valve device embodying a pair of valve parts for simultaneously closing communication between the well and the melting-tank, and opening the passage through the nozzle and vice versa; a shiftable mold; a vacuum-chamber in which the mold is located; means for advancing the mold to its casting position and for withdrawing it therefrom; means for exhausting the vacuum-chamber, and thereby exhausting the space extending from the valve part controlling the passage through the nozzle to the bottom of the mold-space; a power-driven device in the machine; and means operatively connected with said device for actuating the plunger and valve device in proper order.

9. In a casting-machine, the combination with a melting-tank and an outlet-nozzle through which molten metal is discharged, of a well communicating with the melting-tank; a plunger for subjecting molten metal therein to pressure; a valve device embodying a pair of valve parts for simultaneously closing communication between the well and the melting-tank, and opening the passage through the nozzle and vice versa; a shiftable mold; a vacuum-chamber in which the mold is located; means for advancing the mold to its casting position and for withdrawing it therefrom; means for exhausting the vacuum-chamber, and thereby exhausting the space extending from the valve part controlling the passage through the nozzle, to the bottom of the mold-space; a shaft; and springs and means operatively connected with said shaft for controlling the movements of said plunger and said valve device.

10. In a casting-machine, the combination of a plunger for subjecting a mass of molten metal to pressure; a mold, forming a closed mold-space for the injection of molten metal when in its casting position; a valve independent of the mold for controlling the entrance of molten metal to the mold; means for exhausting the closed mold-space extending from the valve to the bottom of the mold-space proper and through and into which the molten metal passes during its flow; a casting-compressor independent of the plunger and operating in unison with said valve; a power-driven device in the machine; and means operatively connected with said device for actuating the plunger and opening and closing the valve in proper order.

11. In a casting-machine, the combination with a melting-tank and an outlet-nozzle through which molten metal is discharged, of a well communicating with the melting-tank; a plunger for subjecting molten metal therein to pressure; a valve device embodying a pair of valve parts for simultaneously closing communication between the well and the melting-tank and opening the passage through the nozzle and vice versa; a mold; means for exhausting the space extending from the valve part controlling the passage through the nozzle to the bottom of the mold-space proper and through and into which the molten metal passes during its flow; a casting-compressor independent of said plunger and operating in unison with said valve; a power-driven device in the machine; and means operatively connected with said device for actuating the plunger and opening and closing the valve in proper order.

12. In a casting-machine, the combination with a melting-tank and an outlet-nozzle through which molten metal is discharged, of a well communicating with the melting-tank; a plunger for subjecting molten metal therein to pressure; a valve device embodying a pair of valve parts for simultaneously closing communication between the well and the melting-tank and opening the passage through the nozzle and vice versa; a mold; means for exhausting the space extending from the valve part controlling the passage through the nozzle to the bottom of the mold-space proper and through and into which the molten metal passes during its flow; a casting-compressor independent of said plunger and operating in unison with said valve; a power-driven device in the machine; and means operatively connected with said device for actuating the plunger and opening and closing the valve in proper order.

eratively connected with such device for actuating the plunger and the valve device in proper order.

12. The combination with a making-tank and an outlet-duct through which molten metal is discharged, of a well communicating with the making-tank; a plunger for subjecting molten metal therein to pressure; a shiftable mold; a vacuum-chamber in which the mold is located; means for advancing the mold to its casting position and for withdrawing it therefrom; a valve for controlling the entrance of molten metal from the well to the mold; a casting-compressor forming an extension of said valve; means for actuating the plunger; means for actuating the valve to close the same and maintain through the casting-compressor a pressure on the molten metal injected into the mold; a power-driven device in the machine; and means operatively connected with such device for causing the actuation in proper order of said means for actuating the plunger and said means for actuating the valve.

13. In a casting-machine, the combination with a making-tank, a well communicating therewith and a plunger for subjecting molten metal therein to pressure, of a shiftable mold; a vacuum-chamber in which the mold is located; an actuator extending through a wall of the vacuum-chamber for actuating the mold; a valve for controlling the entrance of molten metal from the well to the mold; a casting-compressor forming an extension of said valve and terminating when the valve is in its closed position in the plane of the front face of the mold; means for actuating the plunger; means for actuating the valve to close the same and maintain through the casting-compressor a pressure on the molten metal injected into the mold; a power-driven device in the machine; and means operatively connected with such device for causing the actuation in proper order of said means for actuating the plunger and said means for actuating the valve.

14. In a casting-machine, the combination with a mold, of vacuum-producing means; means for filling the mold as soon as a vacuum is produced with molten metal practically instantaneously whereby a high pressure is exerted upon the molten metal and every point in the walls of the mold-space at the moment the mold is filled, a compressor and a compressor-actuator having means for causing a gradually-decreasing force upon the metal in the mold.

15. In a casting-machine, the combination with a mold, of vacuum producing and maintaining means; means for filling the mold as soon as a vacuum is produced practically instantaneously whereby a high pressure is exerted upon the molten metal and every point in the walls of the mold at the moment said mold is filled, and a spring-actuated compressor having means for causing a gradually-decreasing force upon the metal in the mold.

16. In a casting-machine, the combination with a mold and with vacuum-creating means, of mold-filling means; a spring for operating said mold-filling means; a casting-compressor operative on the filling of the mold; a spring for operating said casting-compressor; quick-lift-off means operative momentarily and suddenly to release such springs; and automatic mechanical means for operating the same.

17. In a casting-machine, the combination with a mold and means for raising and axially reciprocating the mold, of means for exhausting the mold and means for filling the exhausted mold with molten metal practically instantaneously, whereby a high pressure is exerted upon the molten metal and every point in the walls of the mold-space at the moment the mold is filled.

18. In a casting-machine, the combination with means for creating a pressure greater than atmospheric upon a mass of molten metal, of a valve-controlled outlet-duct through which molten metal is ejected; a vacuum-chamber into which said metal opens; a mold mounted in said vacuum-chamber to reciprocate toward and away from the outlet-duct; and an exhaust-pipe for exhausting the space of the vacuum-chamber forward of the mold and to which the mold is open when withdrawn from contact with the outlet-duct.

19. In a casting-machine, the combination with means for creating a pressure greater than atmospheric upon a mass of molten metal, of a valve-controlled outlet-duct through which molten metal is ejected; a vacuum-chamber into which said metal opens; a mold mounted in said vacuum-chamber to reciprocate toward and away from the outlet-duct; an exhaust-pipe for exhausting the space of the vacuum-chamber forward of the mold and to which the mold is open when withdrawn from contact with the outlet-duct; and a mold-actuator extending through a stuffing-box in a wall of the vacuum-chamber.

698,592. CASTING-MACHINE. CHAS. E. VERNER, Hartford, Conn. Filed Feb. 14, 1906. Serial No. 5,504. (No model.)

Claim.—1. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric, of an outlet-duct through which molten metal is discharged; a shiftable mold; a vacuum-chamber in which the mold is located; means for advancing the mold to a position when a casting is to be made in which

it contacts with the nozzle, and for withdrawing it therefrom; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting said vacuum-chamber and thereby exhausting the space extending from the valve to the bottom of the mold-space proper and through and into which the molten metal passes during its flow; a power-driven device in the machine, and mechanism operatively connected with such device for actuating the means for advancing the mold, thereby causing same to assume a casting position; then actuating the valve to admit molten metal under pressure to the exhausted mold and subsequently shut off all communication of the metal therewith, and finally actuating the means for withdrawing the mold, thereby withdrawing the mold from its casting position.

2. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than that of atmospheric, of a shiftable mold; a vacuum-chamber in which the mold is located; a stuffing-box in a wall of the vacuum-chamber; a mold-actuator extending through the stuffing-box; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting the vacuum-chamber and thereby exhausting the space extending from the valve to the bottom of the mold-space; a power-driven device in the machine, and mechanism operatively connected with such device for actuating the mold-actuator, thereby causing the mold to assume a casting position; then actuating the valve to admit molten metal under pressure to the exhausted mold, and subsequently shut off all communication of the metal therewith, and finally again actuating the mold-actuator to withdraw the mold from its casting position.

3. In a casting-machine the combination with a making-tank and an outlet-duct through which molten metal is discharged, of a well communicating with said tank; a plunger for subjecting molten metal therein to pressure; a valve device embodying a pair of valve parts for discontinuously closing communication between the well and the making-tank and opening the passage through the nozzle, and vice versa; a shiftable mold; a vacuum-chamber in which the mold is located; means for advancing the mold to its casting position and for withdrawing it therefrom; means for exhausting the vacuum-chamber and thereby exhausting the space extending from the valve part controlling the passage through the nozzle, to the bottom of the mold-space; a power-driven device in the machine, and mechanism operatively connected with such device for actuating the means for advancing and withdrawing the mold, the plunger and the valve device in proper order.

4. In a casting-machine, the combination with a making-tank and an outlet-duct through which molten metal is discharged, of a well communicating with said tank; a plunger for subjecting molten metal therein to pressure; a valve device embodying a pair of valve parts for discontinuously closing communication between the well and the making-tank, and opening the passage through the nozzle, and vice versa; a shiftable mold; a vacuum-chamber in which the mold is located; means for advancing the mold to a position when a casting is to be made, in which it contacts with the nozzle, and for withdrawing it therefrom; means for ex-

hausting the vacuum-chamber and thereby exhausting the space extending from the valve part controlling the passage through the nozzle, to the bottom of the mold-space; a power-driven device in the machine, and mechanism operatively connected with such device for actuating the means for advancing and withdrawing the mold, the plunger and the valve device in proper order.

5. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric, of an outlet-duct through which molten metal is discharged; a shiftable mold embodying a plurality of mold-sections movable in different directions; a vacuum-chamber in which the mold is located; means for advancing the mold to a position, when a casting is to be made, in which it contacts with the nozzle, and for withdrawing it therefrom; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting said vacuum-chamber and thereby exhausting the space extending to the bottom of the mold-space; a power-driven device in the machine, and mechanism operatively connected with such device for actuating the means for advancing the mold, thereby causing the mold to assume a casting position; then actuating the valve to admit molten metal under pressure to the exhausted mold, and subsequently shut off all communication of the metal therewith; then actuating the means for withdrawing the mold thereby withdrawing the mold from its casting position, and for finally separating the mold-sections one from another.

6. In a casting-machine, the combination with a making-tank, and an outlet-duct through which molten metal is discharged, of means for subjecting a mass of molten metal to a pressure greater than atmospheric; a shiftable mold; a vacuum-chamber in which the mold is located; a stuffing-box in the wall of the vacuum-chamber; a mold-actuator extending through the stuffing-box; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting the vacuum-chamber and thereby exhausting the space extending from the valve to the bottom of the mold-space; a main shaft; and a series of cams operatively connected to the shaft and with the means for subjecting the molten metal to pressure, the mold-actuator and the metal-controlling valve, and which actuate the same in the following order, namely: first the mold-actuator to shift the mold into its casting position, then the metal-controlling valve, and the means for subjecting the metal to pressure to admit molten metal under pressure to the exhausted mold, and again and finally the mold-actuator to withdraw the mold from its casting position.

7. In a casting-machine, the combination with a making-tank, and an outlet-duct through which molten metal is discharged, of means for subjecting a mass of molten metal to a pressure greater than atmospheric; a shiftable mold embodying a plurality of mold-sections movable in different directions; a vacuum-chamber in which the mold is located; a stuffing-box in the wall of the vacuum-chamber; a mold-actuator extending through the stuffing-box; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting the vacuum-chamber and thereby exhausting the space extending from the valve to the bottom of the mold-space; a main shaft; and a series of cams operatively connected to the shaft and with the means for subjecting the molten metal to pressure, the mold-actuator and the metal-controlling valve, and which operate the same in the following order, namely: first the mold-actuator to shift the mold into its casting position, then the metal-controlling valve and the means for subjecting the metal to pressure to admit molten metal under pressure to the exhausted mold, and again and finally the mold-actuator to withdraw the mold from its casting position and separate the sections thereof one from the other.

8. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than that of atmospheric, of an outlet-duct through which molten metal is discharged; a shiftable mold embodying a pair of side sections movable in different directions; a vacuum-chamber in which the mold is located; means for advancing the mold to a position, when a casting is to be made, in which it contacts with the nozzle, and for withdrawing it therefrom; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting said vacuum-chamber and thereby exhausting the space extending to the bottom of the mold-space; a power-driven device in the machine, and mechanism operatively connected with such device for actuating the means for advancing the mold, thereby causing the same to assume a casting position; then actuating the valve to admit molten metal under pressure to the exhausted mold, and subsequently shut off all communication of the metal therewith; then actuating the means for withdrawing the mold, thereby withdrawing the mold from its casting position, and for finally separating the said side sections of the mold one from another.

9. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric, of an outlet-duct through which molten metal is discharged; a shiftable mold embodying an end section and a pair of side sections movable in different directions; a vacuum-chamber in which the mold is located; means for advancing the mold to a position, when a casting is to be made, in which

it contacts with the discharge-nozzle, and for withdrawing it therefrom; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting said vacuum-chamber, and thereby exhausting the space extending to the bottom of the mold-space; a power-driven device in the machine, and mechanism operatively connected with such device for actuating the means for advancing the mold, thereby causing the same to assume a casting position; then actuating the valve to admit molten metal under pressure to the exhausted mold, and subsequently shut off all communication of the metal therewith; then actuating the means for withdrawing the mold, thereby withdrawing the mold from its casting position, and for finally separating the side and the end sections of the mold one from another.

10. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric, of an outlet-duct through which molten metal is discharged; a shiftable mold embodying a main casting-forming section and a pair of sprue-forming sections movable relatively to said main section; a vacuum-chamber in which the mold is located; means for advancing the mold to a position, when a casting is to be made, in which it contacts with the nozzle, and for withdrawing it therefrom; a valve independent of the mold for controlling the entrance of molten metal thereto; means for exhausting said vacuum-chamber and thereby exhausting the space extending to the bottom of the mold-space; a power-driven device in the machine, and mechanism operatively connected with such device for actuating the means for advancing the mold, thereby causing the same to assume a casting position; then actuating the valve to admit molten metal under pressure to the casting-mold, and subsequently shut off all communication of the metal therewith; then actuating the means for withdrawing the mold, thereby withdrawing the mold from its casting position, and for finally separating the casting-forming and sprue-forming sections of the mold one from the other.

11. In a casting-machine, the combination with a mold embodying a shiftable main mold-section; a pair of side sections movable in different directions transversely to the line of the shifting movement of the main mold-section, and an auxiliary mold-section movable relatively to and in the line of movement of the main mold-section, of mold-filling means comprising an outlet-duct for supplying molten metal to the mold; and means for shifting the side sections and the auxiliary sections relatively to the main mold-section.

12. In a casting-machine, the combination with a mold embodying a shiftable main mold-section, a pair of side sections movable in different directions transversely to the line of shifting movement of the main mold-section, and an auxiliary mold-section movable relatively to and in the line of movement of the main mold-section, of mold-filling means comprising an outlet-duct for supplying molten metal to the mold; and means for reciprocating said side sections in opposite directions, and said main and auxiliary mold-sections in the same direction at predetermined times.

13. In a casting-machine, the combination with a mold embodying a pair of relatively movable main mold-sections, a pair of side sections movable in different directions transversely to the line of relative movement of the main mold-sections, and an auxiliary mold-section movable relatively to and in the line of relative movement of the main mold-sections, of mold-filling means, comprising an outlet-duct for supplying molten metal to the mold; and means for moving the side sections and the auxiliary section relatively to the main mold-sections.

14. In a casting-machine, the combination with a mold embodying a main mold-section comprising a pair of sections; a pair of side sections movable relatively to the main section and an auxiliary section, of a pair of mold-carriers upon which said side sections are respectively mounted; a second pair of mold-carriers, one supported on the other, and upon which the sections constituting the main mold-section are mounted; a carrier for the auxiliary mold-section; and mechanism for shifting all of said carriers relatively to one another.

15. In a casting-machine, the combination with a separable mold embodying a pair of oppositely-reciprocating side sections and a pair of end sections, of the following instrumentalities successively effective in the order named—viz., mold-filling means, and mold-separating mechanism for reciprocating said side sections in opposite directions and the end sections in different directions in the same direction.

16. In a casting-machine, the combination with a discharge-nozzle and a mold embodying a pair of oppositely-movable sprue-forming mold-sections and a main mold-section transversely to which the sprue-forming sections are movable, of mold-filling means; means for withdrawing the mold from contact with the discharge-nozzle; means for separating the sprue-forming mold-sections; a sprue-separating device movable between the separated sprue-forming sections for parting the sprue from the casting in the main mold-section; a power-driven device in the machine; and mechanism operable therefrom and operatively connected with the sprue-

separating device for actuating the sprue-separating device independently of the movement of the mold.

17. In a casting-machine, the combination with a discharge-nozzle, and a mold embodying a pair of oppositely-movable sprue-forming mold-sections and a main mold-section transversely to which the sprue-forming sections are movable, of mold-filling means; means for withdrawing the mold from contact with the discharge-nozzle; means for separating the sprue-forming mold-sections; a sprue-separating device movable between the separated sprue-forming sections for parting the sprue from the casting in the main mold-section; means for separating the casting from the main mold-section; a power-driven device in the machine; and mechanism operable therefrom and operatively connected with the sprue-separating device, and the means for separating the casting from the main mold-section for actuating the same independently of the movement of the mold.

18. In a casting-machine, the combination with a discharge-nozzle and a mold embodying a pair of sprue-forming mold-sections and a pair of main mold-sections for forming the body of the casting and transversely to which main sections said sprue-forming sections are movable, of mold-filling means; means for withdrawing the mold from contact with the discharge-nozzle; means for separating the sprue-forming mold-sections; a sprue-separating device for parting the sprue from the casting; means for separating the casting from the main mold-sections; a power-driven device in the machine; and mechanism operable therefrom and operatively connected with the sprue-separating device and the means for separating the casting from the main mold-section for actuating the same independently of the movement of the mold.

19. In a casting-machine, the combination, with a separable mold embodying a pair of sprue-forming mold-sections, a main section, and a core, of the following instrumentalities successively effective in the order named—viz., mold-filling means; mold-separating means for separating the sprue-forming mold-sections; a sprue-separating device for parting the sprue and the casting; and means for separating the core and the main section of the mold.

20. In a casting-machine, the combination, with a separable mold embodying a pair of sprue-forming mold-sections, a main section, and a core, of the following instrumentalities successively effective in the order named—viz., mold-filling means; mold-separating means for separating the sprue-forming mold-sections; a sprue-separating device for parting the sprue and the casting; and means for shifting the core relatively to the main section of the mold.

21. In a casting-machine, the combination, with a separable mold embodying a pair of sprue-forming mold-sections, a pair of main sections, and a core, of the following instrumentalities successively effective in the order named—viz., mold-filling means; mold-separating means for separating the sprue-forming mold-sections; a sprue-separating device for parting the sprue and the casting; means for separating the main sections of the mold; and means for shifting the core relatively to one of said main sections.

22. In a casting-machine, the combination, with a separable mold embodying a pair of sprue-forming mold-sections, a pair of main sections, and a core, of the following instrumentalities successively effective in the order named—viz., mold-filling means; mold-separating means for separating the sprue-forming mold-sections; a sprue-separating device for parting the sprue and the casting; means for shifting the core and one of the main sections of the mold in unison relatively to the other main section of the mold; and means for shifting the core relatively to said shifted main section of the mold.

23. In a casting-machine, the combination with a mold embodying a pair of sprue-forming mold-sections and a pair of main mold-sections for forming the body of the casting, and transversely to which main sections said sprue-forming sections are movable, of a discharge-nozzle; mold-filling means; means for withdrawing the mold from contact with the discharge-nozzle; means for separating the sprue-forming mold-sections; a sprue-separating device for parting the sprue from the casting and which is movable across the space between the separated sprue-forming sections; means for separating the main sections of the mold; a casting-stripper; a power-driven device in the machine; and mechanism operable therefrom and operatively connected with the casting-stripper and the sprue-separating device for actuating the same independently of the movement of the mold.

24. In a casting-machine, the combination, with a separable mold embodying a pair of sprue-forming mold-sections and a pair of main sections for forming the body of the casting, of the following instrumentalities successively effective in the order named—viz., mold-filling means; mold-separating means for separating the sprue-forming mold-sections; a sprue-separating device movable between the separated sprue-forming mold-sections for parting the sprue and the casting; means for separating the main sections of the mold; and a casting-stripper movable between the separated main sections of the mold.

25. In a casting-machine, the combination with a mold embodying a main mold-section and a pair of sprue-forming mold-sections movable relatively to the main section, of mold-filling means; means for separating the mold-sections; and mold-cleaning means movable across the space between the separated sprue-forming mold-sections.

26. In a casting-machine, the combination with a mold embodying a main mold-section and a pair of sprue-forming mold-sections movable relatively to the main section, of mold-filling means; means for separating the mold-sections; and a mold-cleaning brush movable across the space between the separated sprue-forming mold-sections.

27. In a casting-machine, the combination, with a separable mold embodying a sprue-forming mold-section and also embodying a main section for forming the body of the casting, of mold-filling means; mold-separating means for separating the sprue and the sprue-forming mold-section; a combined brush and sprue separating device for cleaning a mold-section and parting the sprue and the casting; and means for separating the main section of the mold and the body of the casting.

28. In a casting-machine, the combination with a sectional mold embodying a pair of oppositely-movable mold-sections and with mold-filling means, of a shiftable carriage upon which the mold is mounted; means for separating the sections of the mold; and means for coupling the cheeks of said sections, said carriages being movable with the carriage and moving across the cheeks of the mold-sections during their separating movement.

29. In a casting-machine, the combination with a sectional mold embodying a pair of oppositely-movable mold-sections and with mold-filling means, of a carriage upon which the mold is mounted; means for separating the sections of the mold; and means for coupling the cheeks of said sections during their separating movement.

30. In a casting-machine, the combination, with a mold embodying a pair of oppositely-disposed mold-sections, of mold-filling means; mold-separating means for shifting said mold-sections in opposite directions; and a pair of oppositely-disposed mold-scrapers for scraping the cheeks of said mold-sections.

31. In a casting-machine, the combination, with mold-filling means having a discharge-nozzle for supplying molten metal to the mold, of a separable mold embodying a pair of complementary sprue-forming mold-sections movable toward and from each other and also movable toward and from said nozzle to bring the cheeks of said mold-sections into engagement with, and carry them away from, the face of said nozzle, and means for scraping said cheeks of the mold-sections.

32. In a casting-machine, the combination, with mold-filling means having a discharge-nozzle for supplying molten metal to the mold, of a separable mold embodying a pair of complementary sprue-forming mold-sections movable toward and from each other and also movable toward and from said nozzle to bring the cheeks of said mold-sections into engagement with, and carry them away from, the face of said nozzle, and a pair of mold-scrapers effective respectively for scraping said cheeks of the mold-sections.

33. In a casting-machine, the combination, with a vacuum-chamber having a plurality of openings therein, of a separable mold located within said chamber and embodying a plurality of mold-sections; means for filling said mold with molten metal and exerting a high pressure upon the latter and every point in the walls of the mold-space at the moment of complete filling of the mold; a plurality of operating members working respectively in said openings; air-tight packings between the operating members and the walls of said openings; a main mold-carrier for one of said mold-sections; a plurality of auxiliary mold-sections supported on the main mold-carrier and each supporting a different mold-section; and connecting means between the respective operating members and the several mold-sections.

34. In a casting-machine, the combination, with a vacuum-chamber having a plurality of openings therein, of a separable mold located within said chamber and embodying a plurality of mold-sections; means for filling said mold with molten metal and exerting a high pressure upon the latter and every point in the walls of the mold-space at the moment of complete filling of the mold; a plurality of operating members working respectively in said openings; air-tight packings between the operating members and the walls of said openings; a main mold-carrier for one of said mold-sections; an auxiliary mold-carrier supported on the main mold-carrier and carrying a mold-section; a core-carrier also supported on the main mold-carrier and carrying a core-section; and connections from the respective operating members to the mold-carriers and the core-carrier.

35. In a casting-machine, the combination, with a vacuum-chamber having a plurality of openings therein, of a separable mold located within said chamber and embodying a plurality of mold-sections; mold-filling means; a casting-stripper also located within said chamber; a plurality of operating members working respectively in said openings; air-tight packings between the operating members and the walls of the openings;

and connections from the respective operating members to the mold-sections and the casting-stripper.

36. In a casting-machine, the combination, with a vacuum-chamber having a plurality of openings therein, of a separable mold located within said chamber and embodying a plurality of mold-sections; mold-filling means; mold-cleaning means and a casting-stripper also located within said chamber; a plurality of operating members working respectively in said openings; air-tight packings between the operating members and the walls of the openings; and connections from the respective operating members to the mold-sections, the mold-cleaning means, and the casting-stripper.

37. In a casting-machine, the combination, with a vacuum-chamber having a plurality of openings therein, of a separable mold located within said chamber and embodying a plurality of mold-sections; mold-filling means; a sprue-separating device and a casting-stripper also located within said chamber; a plurality of operating members working respectively in said openings; air-tight packings between the operating members and the walls of the openings; and connections from the respective operating members to the mold-sections, the sprue-separating device, and the casting-stripper.

38. In a casting-machine, the combination, with a vacuum-chamber having a plurality of openings therein, of a separable mold located within said chamber and embodying a plurality of mold-sections; mold-filling means; a plurality of differentially-effective spring-pressed operating members working in said openings and controlling respectively said mold-sections; and air-tight packings between said operating members and the walls of said openings.

39. In a casting-machine, the combination, with a vacuum-chamber having an opening therein, of a separable mold located within said chamber and embodying a plurality of mold-sections; mold-filling means; means for separating the mold-sections; a stripper-operating shaft working in said opening in the chamber; an air-tight packing between said shaft and the walls of said opening; and a casting-stripper located within said chamber and effective on the separation of said mold-sections.

40. In a casting-machine, the combination with an outlet-nozzle, of a mold embodying side sections movable in opposite directions and a main section movable transversely to the direction of movement of the side sections; yielding means for exerting pressure upon the mold and the mold-sections during the filling of the mold; a power-driven device in the machine; cam-follower actuators operatively connected with each device for withdrawing the mold from the outlet-nozzle; and other cam-follower actuators for separating the sections of the mold one from the other independently of the backward movement of the mold from the outlet-nozzle.

41. In a casting-machine, the combination with an outlet-nozzle and a mold embodying a pair of side sections and a main section, of springs for pressing the side sections together; means for pressing the mold yieldingly against the nozzle; a power-driven device in the machine; a cam-follower actuator operatively connected with each device for withdrawing the same from the outlet-nozzle; and other cam-follower actuators for separating the sections of the mold one from the other independently of the backward movement of the mold from the outlet-nozzle.

42. In a casting-machine, the combination, with mold-filling means, of a separable mold embodying a pair of spring-pressed side sections, a pair of spring-pressed and cushion movable transversely to the side sections, and a spring-pressed core also movable transversely to the side sections.

43. In a casting-machine, the combination, with a mold and with mold-filling means, of mechanism for positioning one of said elements relatively to the other, and an electromagnetic safety device effective reciprocally with said positioning mechanism and governed by the position of said elements and operative for preventing filling of the mold when said element is improperly positioned.

44. In a casting-machine, the combination, with an electric circuit having a normally open break, of a separable mold embodying a pair of mold-sections adapted when closed to close said break in the circuit; mold-filling means; mold-cleaning means; and an electromagnetic safety device controlled by said circuit and normally operative for breaking the operation of the mold-filling means.

45. In a casting-machine, the combination, with an electric circuit having two normally open breaks therein, of a separable mold embodying a plurality of mold-sections adapted when closed to close said breaks in the circuit; mold-filling means; mold-cleaning means; and an electromagnetic safety device controlled by said circuit and normally operative for breaking the operation of the mold-filling means.

46. The combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and vacuum-maintaining, casting receiving and discharging means sealing said opening and operative alternately for receiving and discharging castings.

47. The combination, with a vacuum-chamber having an opening, of a mold located within said chamber; mold-filling means; and liquid-

containing, vacuum-maintaining, casting receiving and discharging means forming a liquid seal for said opening and operative alternately for receiving and discharging castings.

48. The combination, with a receptacle and with a vacuum-chamber adapted to communicate therewith, of a mold located within said vacuum-chamber; mold-filling means; and a valve controlling communication between said receptacle and the vacuum-chamber and having a casting-receiving chamber.

49. The combination, with a vacuum-chamber open at its lower end, of a mold located within said chamber; mold-filling means; a receptacle at the open end of said chamber; and a valve controlling communication between said receptacle and the vacuum-chamber and having a casting-receiving chamber normally located under the mold.

50. The combination, with a vacuum-chamber and with an open liquid-containing receptacle communicating therewith, of a mold located within said chamber; mold-filling means; and a valve controlling communication between said receptacle and the vacuum-chamber and having a liquid-containing, casting-receiving chamber.

51. The combination, with a vacuum-chamber having an opening, of a separable mold located within said chamber; mold-filling means; mechanism for opening and closing the mold; and vacuum-maintaining, casting receiving and discharging means sealing said opening and operative alternately for receiving and discharging castings.

52. The combination, with a vacuum-chamber having a discharge-opening, of a mold located within said chamber; mold-filling means; and a casting-receiving valve controlling communication between said discharge-opening and the outside atmosphere.

53. The combination, with a vacuum-chamber having a discharge-opening, of a mold located within said chamber; mold-filling means; and a casting-receiving valve open at one side only and controlling communication between said discharge-opening and the outside atmosphere.

54. The combination, with a vacuum-chamber open at its lower end, of a mold located within said chamber; mold-filling means; and a casting-receiving valve adapted to seal the open end of said chamber and controlling communication therewith.

55. The combination, with a vacuum-chamber having a discharge-opening, of a mold located within said chamber; mold-filling means; and an oscillatory casting-receiving valve controlling communication between said discharge-opening and the outside atmosphere.

56. The combination, with a vacuum-chamber having a discharge-opening, of a mold located within said chamber; mold-filling means; and an oscillatory casting-receiving plug-valve controlling communication between said discharge-opening and the outside atmosphere.

57. The combination, with a vacuum-chamber having a discharge-opening, of a mold located within said chamber; mold-filling means; an oscillatory casting-receiving valve controlling communication between said discharge-opening and the outside atmosphere and having a projecting stem; and an air-tight packing surrounding said stem.

58. The combination, with a vacuum-chamber having a discharge-opening, of a mold located within said chamber; mold-filling means; and an oscillatory casting-receiving valve controlling communication between said discharge-opening and the outside atmosphere; and means for flushing the movements of said valve.

59. In a casting-machine, the combination with a vacuum-chamber having an opening in one of its walls, of a mold located in the vacuum-chamber; mold-filling means embodying a removable discharge-nozzle projecting into said opening in the vacuum-chamber; an annular member secured to the vacuum-chamber over said opening in the wall of the chamber and provided with a retaining-channel adjacent to the edge of the opening; a clamping-ring engaging with the removable nozzle and positively securing the same to the mold-filling means; means for securing said clamping-ring to said annular member; and a heat-insulating packing located in said retaining-channel in the annular member and in contact with the edge of the opening in the wall of the vacuum-chamber to thereby maintain an air-tight joint between the wall of the vacuum-chamber and the said annular member during the expansion and contraction of the parts.

698,592. MOLD MECHANISM. CLARENCE H. VANDER BARTHOLOMEW. Filed May 19, 1899. Serial No. 17,312. (No model.)

Claim.—1. In a casting-machine, the combination with a separable mold, embodying a pair of main dies movable in different directions, and an auxiliary die movable relatively to and in the path of one of said main dies, of a driving-shaft and cam-follower actuators operable therefrom, and operatively connected with the dies whereby the main dies and the auxiliary die are caused to move in proper sequence during the running of the machine.

2. The combination, with a separable mold embodying a pair of main dies movable in different directions and a pair of auxiliary dies movable

relatively to and in the paths of said main die, of mold-filling means and means for shifting first one of said auxiliary dies and then the corresponding main die, and afterward the other auxiliary die and its corresponding main die.

2. In a casting-machine, the combination with a separable and shiftable mold embodying a pair of main casting-forming dies movable in different directions and also embodying an auxiliary die movable relatively to one of said main dies, of mold-filling means for supplying molten metal in the mold, a carriage movable toward and from the mold-filling means, a pair of main die-carriers mounted on and movable relatively in said carriage and respectively supporting said main dies, an auxiliary die-carrier assembled with one of said main die-carriers and supporting the auxiliary die, a driving-shaft, and cam-face actuators operable therefrom for actuating the mold-carriage to advance the same to its casting position and withdraw it therefrom, and independent cam-face actuators for actuating said die-carriers when said carriage has been withdrawn from its casting position and thereby separate the main casting-forming dies and withdraw the auxiliary die.

4. A separable mold embodying a pair of complementary sprue-forming dies at least one of which has a sprue-forming opening therein, said dies also having registering die-receiving openings therein and complementary casting-forming dies seated respectively in said openings, at least one of said casting-forming dies having a die-space therein, and automatic mechanisms for opening said mold by withdrawing first one casting-forming die, then its companion sprue-forming die, and afterward the other casting-forming die, and finally the other sprue-forming die.

5. In a casting-machine, the combination with a separable mold, embodying a pair of main dies and an auxiliary die carried by one of said main dies and movable relatively therein, of a spring and stop-flange for controlling the relative movements of said auxiliary die and the main die upon which it is carried, a driving-shaft, and cam-face actuators operable therefrom for shifting the position of the auxiliary die and thereby effect the movement of the main die by which the auxiliary die is carried.

6. In a casting-machine, the combination with a separable mold, embodying a pair of complementary main dies and a pair of auxiliary dies assembled respectively with said main dies, of main and auxiliary die-carriers for said dies, each pair of die-carriers being movable relatively to each other, springs and stop-flanges for controlling the relative movement of the respective pairs of main die-carriers and auxiliary die-carriers, a driving-shaft and cam-face actuators operable therefrom for positively actuating the auxiliary die-carriers.

7. The combination, with a separable mold embodying a pair of complementary main dies and a pair of auxiliary dies carried respectively by said main dies, of main and auxiliary die-carriers for said respective dies; spring-pressed means for automatically operating corresponding die-carriers; each main die-carrier and its auxiliary die-carrier also having a spring interposed between them.

8. In a casting-machine, the combination, with a mold-filling means having a discharge-opening, of a casting-support separate from the mold and located wholly without the mold-space and disposed in the meeting line of the dies; a separable mold embodying a pair of side dies having a mold-space communicating with said discharge-opening and closable by said support; and means for separating said dies by a movement transverse to such casting-support.

9. In a casting-machine, the combination, with mold-filling means having a discharge-opening, of a casting-support opposite said discharge-opening and located wholly without the mold-space and disposed in the meeting line of the dies; a separable mold embodying a pair of side dies having a mold-space communicating with said discharge-opening and closable by said support; and means for separating said dies by a movement transverse to such casting-support.

10. In a casting-machine, the combination, with mold-filling means having a discharge-opening at one end of the sprue-opening, of a support at the other end of the sprue-opening and located wholly without the mold-space; a separable mold embodying a pair of sprue-forming dies

having sprue-channels one communicating with said discharge-opening and the other closable by said support; and means for separating said dies while the casting is contained by said support.

11. In a casting-machine, the combination, with mold-filling means having a discharge-opening at one end of the sprue-opening, of a pin at the other end of the sprue-opening; a separable mold embodying a pair of sprue-forming side dies having sprue-channels one communicating with said discharge-opening and the other closable by said pin; and means for separating said dies while the casting is contained by said pin.

12. In a casting-machine, the combination, with mold-filling means having a discharge-opening at one end of the sprue-opening, of an adjustable pin at the other end of the sprue-opening; a separable mold embodying a pair of sprue-forming side dies having sprue-channels one communicating with said discharge-opening and the other closable by said pin; and means for separating said dies while the casting is contained by said pin.

13. In a casting-machine, the combination with mold-filling means having a discharge-opening at one end of the sprue-opening, of a centering-pin adjustable transversely to, and less diameter with, said discharge-opening and located at the other end of the sprue-opening; a separable mold embodying a pair of sprue-forming side dies having sprue-channels communicating with opposite sides of the mold-space, one communicating with said discharge-opening and the other closable by said centering-pin; and means for separating said dies while the casting is contained by said centering-pin.

14. In a casting-machine, the combination, with mold-filling means having a discharge-opening at one end of the sprue-opening, of a mold-carriage movable toward and from said discharge-opening; a pin on said carriage and located at the other end of the sprue-opening; a separable mold on said carriage and embodying a pair of sprue-forming side dies having sprue-channels one communicating with said discharge-opening and the other closable by said pin; and means for separating said dies while the casting is contained by said pin.

15. In a casting-machine, the combination, with a mold embodying a pair of dies, of mold-filling means; mold-separating means for shifting said dies in different directions; and a pair of mold-carpers movable relatively to and across the cheeks of said dies.

16. In a casting-machine, the combination, with a mold embodying a pair of dies, of mold-filling means; mold-separating means for shifting said dies in different directions; a pair of mold-carpers movable relatively to and across the cheeks of said dies; and scraper-actuating means for advancing said carpers toward each other during the opening of the dies.

17. In a casting-machine, the combination, with a mold embodying a pair of dies, of mold-filling means; mold-separating means for shifting said dies in different directions; a pair of mold-carpers movable relatively to and across the cheeks of said dies; and scraper-actuating means for advancing said carpers toward each other during the opening of the dies.

18. In a casting-machine, the combination, with a mold embodying a pair of oppositely-disposed dies, of mold-filling means; mold-separating means for shifting said dies in different directions; a pair of oppositely-disposed mold-carpers movable relatively to and across the cheeks of said dies; and scraper-actuating means for advancing said carpers toward each other while the dies are separated.

19. In a casting-machine, the combination, with a mold embodying a pair of sprue-forming dies, of mold-filling means having a discharge-opening; mold-separating means for shifting said dies in different directions; and a pair of mold-carpers movable relatively to and across those cheeks of the dies which coast with the face of said discharge-opening.

698,598. ARTHUR FURNING GARDNER. CHAS. E. VERNER, Hartford, Conn. Filed May 21, 1906. Serial No. 17,851. (No model.)

Claim.—1. This improvement in the art of making a casting which consists in projecting the molten metal into and against the walls of the mold by a ram-like action produced by first setting in motion a body of molten metal in a direction other than into the mold, and afterward, subsequent to the establishment of such flow, instantly diverting the direction of flow of the entire body of moving metal into the mold, whereby the kinetic energy of the entire mass of moving metal becomes effective to increase the impact of the entering metal.

2. That improvement in the art of making a casting, which consists in first exhausting the mold and in then projecting the molten metal into and against the walls of the exhausted mold by a ram-like action produced by first setting in motion a body of molten metal in a direction other than into the mold, and then, subsequent to the establishment of such flow, instantly diverting the direction of flow of the entire body of moving metal into the mold, whereby the kinetic energy of the entire mass of moving metal becomes effective to increase the impact of the entering metal.

3. That improvement in the art of making a casting which consists in projecting the molten metal into and against the walls of the mold by a ram-like action produced by maintaining a closing pressure upon the

valve which controls the ejection of the molten metal and during this time establishing a movement in a body thereof in a direction other than into the mold, and afterward, subsequent to the establishment of such flow, instantly releasing the pressure on the valve, thereby permitting the instantaneous diversion of the direction of flow of the entire body of moving metal into the mold, and in continuing the application of the force by which such movement in the body of metal is accomplished during the open position of the valve.

4. That improvement in the art of making a casting which consists in projecting the molten metal into and against the walls of the mold by a ram-like action produced by maintaining a closing pressure upon the valve which controls the ejection of the molten metal and during this time establishing a movement in a body thereof in a direction other than into the mold, and afterward, subsequent to the establishment of such flow, instantly releasing the pressure on the valve, thereby permitting the instantaneous diversion of the direction of flow of the entire body of moving metal into the mold, and in continuing the application of the force by which such movement in the body of metal is accomplished, during the open position of the valve, and in cooling the casting during the setting of the metal.

5. That improvement in the art of making a casting which consists in projecting the molten metal into and against the walls of the mold by a ram-like action produced by maintaining a closing pressure upon the valve which controls the ejection of the molten metal and during this time establishing a movement in a body thereof in a direction other than into the mold, and afterward, subsequent to the establishment of such flow, instantly releasing the pressure on the valve, thereby permitting the instantaneous diversion of the direction of flow of the entire body of moving metal into the mold, and in continuing the application of the force by which such movement in the body of metal is accomplished, during the open position of the valve, and also continuing the pressure on the casting and cooling the same during the setting of the metal.

6. That improvement in the art of making a casting which consists in operating the pistons of air-pumps communicating with the mold and opening the valve in the passage-way leading from one pump to the mold, in then closing this valve and opening the valve in the passage-way leading from another air-pump to the mold, in projecting the molten metal into and against the walls of the exhausted mold by a ram-like action produced by first setting in motion a body of molten metal in a direction other than into the mold, and maintaining a pressure during this operation on the valve controlling the injection of molten metal, and finally, after said second-mentioned valve in the passage-way leading to the second pump has been opened, suddenly releasing the pressure on said metal-controlling valve, thereby permitting the instantaneous diversion of the direction of flow of the entire body of moving metal into the mold.

7. That improvement in the art of making a casting, which consists in first exhausting the mold, in then projecting the molten metal into and against the walls of the exhausted mold by a ram-like action produced by first setting in motion a body of molten metal in a direction other than into the mold, and after the mold is exhausted and such flow inaugurated, instantly diverting the direction of flow of the entire body of moving

metal into the mold, and in cooling the casting during the setting of the metal.

8. That improvement in the art of making a casting which consists in operating the pistons of air-pumps communicating with the mold and opening the valve in the passage-way leading from one pump to the mold, and then closing this valve and opening the valve in the passage-way leading from another air-pump to the mold, in projecting the molten metal into and against the walls of the exhausted mold by a ram-like action produced by first setting in motion a body of molten metal in a direction other than into the mold and during this operation maintaining a pressure on the valve controlling the injection of molten metal and then suddenly releasing the pressure on said metal-controlling valve after the second-mentioned valve in the passage-way leading to the second pump has been opened, thereby permitting the instantaneous diversion of the direction of flow of the entire body of moving metal into the mold and in continuing the application of the force which sets said body of molten metal in motion after said metal-controlling valve has been opened.

9. That improvement in the art of making a casting which consists in operating the pistons of air-pumps communicating with the mold and opening the valve in the passage-way leading from one pump to the mold, in then closing this valve and opening the valve in the passage-way leading from another air-pump in the mold, in setting in motion a body of molten metal in a direction other than into the mold, in maintaining a pressure on the valve controlling the injection of molten metal during this operation, in suddenly releasing the pressure on said metal-controlling valve after the second-mentioned valve in the passage-way leading to the second pump has been opened, thereby permitting the instantaneous diversion of the direction of flow of the entire body of moving metal into the mold, and in continuing a pressure on the casting during the setting of the metal.

10. That improvement in the art of making a casting, which consists in first exhausting the mold, in then projecting the molten metal into and against the walls of the exhausted mold by a ram-like action produced by establishing a movement in a body of molten metal in a direction other than into the mold, and then, after the mold is exhausted and such flow is inaugurated, instantly diverting the direction of flow of the entire body of moving metal into the mold, and in cooling the casting and maintaining a pressure thereon during the setting of the metal.

698,594. HENRY MECHANISM. CHAS. E. VERNER, Hartford, Conn. Filed May 21, 1906. Serial No. 17,860. (No model.)

Claim.—1. In a separable mold, the combination with a pair of complementary main mold-sections, one of which is reciprocatory toward and from the other in a straight line, of an auxiliary mold-section assembled with said reciprocatory main mold-section, a core fixed relatively to said reciprocatory main mold-section and movable therewith relatively to said auxiliary mold-section, and means for moving said auxiliary section, the core-section and the reciprocatory main mold-section as a unit during the first portion of the backward movement of the reciprocatory main mold-section, and for causing the main reciprocatory section and the core to move relatively to the auxiliary section, as the main mold-section moves the end of its backward reciprocation.

2. In a separable mold, the combination with a pair of complementary main mold-sections, one of which is reciprocatory toward and from the other in a straight line, of an auxiliary mold-section assembled with said reciprocatory main mold-section, a core fixed relatively to said reciprocatory main mold-section and movable therewith relatively to said auxiliary mold-section, means for moving the reciprocatory main mold-section, the core and the auxiliary section as a unit, and means for arresting the movement of the auxiliary section during the last portion of the backward movement of the reciprocatory main mold-section, thereby permitting said main section and the core to move relatively to the auxiliary section.

3. In a separable mold, the combination with a pair of oppositely-disposed complementary main mold-sections facing each other and one of which is reciprocatory toward and from the other, of an auxiliary mold-section assembled with said reciprocatory main mold-section, a core fixed relatively to said main mold-section and movable therewith relatively to said auxiliary mold-section, and means for moving said auxiliary mold-section and the core.

4. In a separable mold, the combination, with a pair of oppositely-disposed complementary main mold-sections, of a mold-section removably attached to one of said main mold-sections and to project beyond the face of such attached mold-section when the mold is fully opened; a core-section movable within said auxiliary mold-section; and means for movably supporting all of said mold-sections.

5. In a separable mold, the combination with a pair of complementary main mold-sections, one of which is reciprocatory toward and from the other in a straight line, of an auxiliary mold-section assembled with the reciprocatory main mold-section, a spring interposed between the assembled sections, a core fixed relatively to said reciprocatory main mold-section and movable therewith relatively to said auxiliary mold-section, and means comprising a fixed stop for arresting the movement of the auxiliary section, thereby permitting the other sections to move near the end of the backward movement of the main mold-section.

6. The combination, with a mold-carrier, of an auxiliary mold-section secured to said mold-carrier; a pair of oppositely-disposed complementary main mold-sections, one of which is reciprocatory on said carrier toward and from the other and relatively to said auxiliary mold-section; a second auxiliary mold-section shiftable relatively to one of said other mold-sections; and means for movably supporting the mold-sections and for actuating said reciprocatory main mold-section.

7. The combination, with a mold-carrier, of a tubular auxiliary die secured to said mold-carrier; a pair of oppositely-disposed complementary main mold-sections one of which is reciprocatory on said carrier toward and from the other and relatively to said tubular auxiliary mold-section; a core mounted in said tubular mold-section and fixed to said main mold-section; and means for movably supporting the mold-sections and core and for actuating said reciprocatory main mold-section.

8. The combination, with a mold-carrier, of a tubular auxiliary die secured to said mold-carrier; a pair of oppositely-disposed complementary main mold-sections one of which is reciprocatory on said carrier toward and from the other and relatively to said auxiliary mold-section; a core mounted in said tubular mold-section and fixed to said main mold-section; and means for movably supporting the mold-sections and core and for actuating said reciprocatory main mold-section.

9. The combination, with a mold-carrier, of a tubular auxiliary die secured to said mold-carrier; a pair of oppositely-disposed complementary main mold-sections one of which is reciprocatory on said carrier toward and from the other and relatively to said auxiliary mold-section; a core mounted in said tubular die and fixed to said main mold-section and movable therewith in one direction and then in the opposite direction to strip the casting from the mold; and means for movably supporting the mold-sections and core and for actuating said reciprocatory main mold-section.

10. The combination, with a mold-carrier, of a tubular auxiliary mold-section secured to said mold-carrier; a main mold-section shiftable on said carrier relatively to said auxiliary mold-section; a core mounted in said tubular mold-section and fixed to said main section; and a spring between said mold-carrier and the main mold-section.

11. The combination, with a mold-carrier, of a tubular auxiliary mold-section secured to said mold-carrier; a main mold-section shiftable on said carrier relatively to said auxiliary mold-section; a core mounted in said tubular mold-section and fixed to said main section and movable therewith; a stop for limiting the movement of the mold-carrier in one direction; a spring between the mold-carrier and the main mold-section for shifting said main section and the core in one direction relatively to said auxiliary mold-section; and means for shifting said main mold-section in the opposite direction in opposition to the force of such spring to strip a casting from the mold.

698,595. MOLD MECHANISM. CURTIS E. VERNER, Hartford, Conn. Filed May 22, 1900. Serial No. 17,864. (No model.)

Claim.—1. In a mold, the combination with a mold-section, of a pair of reciprocatory and relatively movable mold-sections; a fixed stop and a coacting face for limiting the movement in one direction of one section of said pair of mold-sections; a separate stop and coacting face for limiting the movement of this section in the opposite direction; means for positively reciprocating this section; and steps and coacting faces for limiting the relative movement of said pair of reciprocatory sections at the close of the movement in both directions of the positively-reciprocated section.

2. In a mold, the combination with a mold-section, of a pair of re-

ciprocatory and relatively movable mold-sections; mold-carriers for supporting said pair of mold-sections; a fixed stop and a coacting face for limiting the movement in one direction of one of said carriers; a separate stop and coacting face for limiting the movement of this carrier in the opposite direction; means for positively reciprocating this carrier; and steps and coacting faces for limiting the relative movement of said carriers at the close of the movement in both directions of the positively-reciprocated carrier.

3. In a mold, the combination, with a mold-section, of a pair of mold-sections being said first mold-section and complementary thereto and co-acting directly with each other; a mold-carrier for movably supporting said first mold-section; a pair of co-operative mold-carriers movable together and also relatively to each other and supporting said pair of mold-sections respectively; means for limiting the movements of one of said pair of mold-carriers; and means for limiting the relative movement of the other mold-carrier of said pair.

4. In a mold, the combination, with a mold-section, of a pair of mold-sections being said first mold-section and complementary thereto and co-acting directly with each other; a mold-carrier for movably supporting said first mold-section; a pair of co-operative mold-carriers one mounted on the other and movable together and also relatively to each other and supporting said pair of mold-sections respectively; means for limiting the movements of one of said pair of mold-carriers; and means for limiting the relative movement of the other mold-carrier of said pair.

5. In a mold, the combination, with a mold-section, of a pair of mold-sections being said first mold-section and complementary thereto and co-acting directly with each other; a mold-carrier for movably supporting said first mold-section; mold-carriers movable relatively to each other and supporting said pair of mold-sections respectively, one of which mold-carriers is tubular and is mounted on the other; means for limiting the movements of one of said pair of mold-carriers; and means for limiting the relative movement of the other mold-carrier of said pair.

6. In a mold, the combination, with a mold-section, of a pair of mold-sections being said first mold-section and complementary thereto and co-acting directly with each other; a mold-carrier for movably supporting said first mold-section; mold-carriers movable relatively to each other and supporting said pair of mold-sections respectively, one of which mold-carriers is tubular and is mounted on the other, and one of which is operative for actuating the other, said operating mold-carrier having a transverse slot; a transverse key carried by the operated mold-carrier and working in said slot in the operating mold-carrier; and means for limiting the movements of said operating mold-carrier.

7. The combination, with a main mold-section and with a core, of an auxiliary mold-section assembled therewith; a tubular main mold-carrier supporting said main mold-section and the core and having a transverse slot; an auxiliary mold-carrier supporting said auxiliary mold-section and mounted to slide in the main mold-carrier and having a transverse key working in said slot in the main mold-carrier; and means for limiting the movements of said auxiliary mold-carrier.

8. A separable mold comprising a pair of complementary main mold-sections one provided with a sprue-forming mold-space and the other with a casting-forming mold-space; an auxiliary mold-section co-operative with one of said main mold-sections; a mold-carrier for movably supporting one of said main mold-sections; and a pair of co-operative mold-carriers movable together and also relatively to each other and supporting the other main mold-section and the auxiliary mold-section.

9. A separable mold comprising a pair of complementary mold-sections, one provided with a sprue-forming mold-space and the other with a casting-forming mold-space; a core-section fixed with relation to one of said mold-sections; an auxiliary mold-section movable with relation to the core-section and the mold-section relatively to which the core-section is fixed; mold-section carrier for movably supporting the various mold-sections, the carrier supporting the core-section also supporting the main section relatively to which the core-section is fixed; means for positively reciprocating one of the carriers; and means for limiting the relative movement of said auxiliary section carrier and said core and main section carrier at the close of the movement in both directions of the positively-reciprocated carrier.

10. A separable mold comprising a pair of complementary main mold-sections, one provided with a sprue-forming mold-space and the other with a casting-forming mold-space; a pair of auxiliary mold-sections co-operative with one of said main mold-sections; and a pair of co-operative mold-carriers adapted to move together and also with relation to each other, one of this pair of co-operative mold-carriers supporting the remaining main mold-section and also one of the auxiliary mold-sections, and the other of said pair of co-operative mold-carriers supporting the other auxiliary mold-section.

11. A separable mold comprising a pair of complementary main mold-sections, one provided with a sprue-forming mold-space, and the other

with a casting-forming mold-space; an auxiliary mold-section and a core-section co-operative with one of said main mold-sections; a mold-carrier for movably supporting one of said main mold-sections; a mold-carrier for movably supporting the other main mold-section and also the core-section; and a carrier supporting the other auxiliary mold-section and movable relatively to said last-mentioned main mold-section, and came said auxiliary mold-section to project beyond the face of the co-operative main and core sections when the mold is open.

698,596. CASTING-MACHINE. CURTIS E. VERNER, Hartford, Conn. Filed Jan. 22, 1900. Serial No. 2,486. (No model.)

Claim.—1. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric, a mold, of a plurality of air-pumps for producing a vacuum therein; a valve for controlling the entrance to the exhausted mold of molten metal; a power-driven device in the machine; and mechanism operatively connected with such device which first renders one of the air-pumps effective to exhaust the mold, then renders such pump ineffective and a second pump effective to further exhaust the partially-exhausted mold, and finally during the second exhaustion actuates the said valve and thereby admits molten metal under pressure to the mold.

2. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric, and a mold, of a plurality of air-pumps communicating with the mold for producing a vacuum therein; valves controlling the passage-ways leading from the air-pump cylinders to the mold; a valve for controlling the entrance to the exhausted mold of molten metal; a power-driven device in the machine; and mechanism operatively connected with such device, which first actuates the pistons of the air-pumps, and opens the valve in the passage-way leading from one of the air-pump cylinders to the mold, then closes this latter valve and opens the valve in the passage-way leading from the second air-pump cylinder to the mold, and finally, before the piston of the last-mentioned cylinder has reached the end of its stroke, opens said valve controlling the flow of molten metal to the mold.

3. In a casting-machine, the combination with a plunger for subjecting molten metal to pressure, and a mold, of a plurality of air-pumps communicating with the mold for producing a vacuum therein; valves controlling the passage-ways leading from the air-pump cylinders to the mold; a valve for controlling the entrance to the exhausted mold of molten metal; a power-driven device in the machine; and mechanism operatively connected with such device, which first actuates the pistons of the air-pumps and opens the valve in the passage-way leading from one of the cylinders to the pump, then closes this latter valve and opens the valve in the passage-way leading from a second air-pump cylinder to the mold, then, before the piston of the last-mentioned cylinder has reached the end of its stroke, actuates the plunger and opens the said metal-controlling valve, and finally opens said air-valve and admits air to the mold.

the air-pump cylinders in the mold, then closes this latter valve and opens the valve in the passage-way leading from a second air-pump cylinder, and finally, before the piston of the last-mentioned cylinder has reached the end of its stroke, actuates the plunger and opens said valve controlling the flow of molten metal to the mold.

4. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric, a mold, and an air-valve for admitting air to the mold at a predetermined time, of a plurality of air-pumps for producing a vacuum in the mold; a valve for controlling the entrance to the exhausted mold of molten metal; a power-driven device in the machine; and mechanism operatively connected with such device which first renders one of the air-pumps effective to exhaust the mold, then renders such pump ineffective and a second pump effective to further exhaust the partially-exhausted mold, then during the second exhaustion actuates the said metal-controlling device and admits molten metal to the mold, and finally opens said air-valve and admits air to the mold.

5. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric, a mold, and an air-valve for admitting air to the mold at a predetermined time, of a plurality of air-pumps communicating with the mold for producing a vacuum therein; valves controlling the passage-ways leading from the air-pump cylinders to the mold; a valve for controlling the entrance to the exhausted mold of molten metal; a power-driven device in the machine; and mechanism operatively connected with such device which first actuates the pistons in the air-pumps and opens the valve in the passage-way leading from one of the air-pump cylinders to the mold, then closes this latter valve and opens the valve in the passage-way leading from a second cylinder to the mold, then, before the piston of the last-mentioned cylinder has reached the end of its stroke, opens the said metal-controlling valve, and finally opens said air-valve and admits air to the mold.

6. In a casting-machine, the combination with a plunger for subjecting molten metal to pressure, a mold, and an air-valve for admitting air to the mold at a predetermined time, of a plurality of air-pumps communicating with the mold for producing a vacuum therein; valves controlling the passage-ways leading from the air-pump cylinders to the mold; a valve for controlling the entrance to the exhausted mold of molten metal; a power-driven device in the machine; and mechanism operatively connected with such device which first renders the pistons of the air-pumps and opens the valve in the passage-way leading from one of the cylinders to the pump, then closes this latter valve and opens the valve in the passage-way leading from a second air-pump cylinder to the mold, then, before the piston of the last-mentioned cylinder has reached the end of its stroke, actuates the plunger and opens the said metal-controlling valve, and finally opens said air-valve and admits air to the valve.

7. In a casting-machine, the combination with a plunger for subjecting molten metal to pressure, and a mold, of a plurality of air-pumps communicating with the mold for producing a vacuum therein; valves controlling the passage-ways leading from the air-pump cylinders to the mold; a valve for controlling the entrance into the exhausted mold of molten metal; a main shaft from which the pistons of said air-pump cylinders are actuated; and a series of cams operatively connected to the shaft, and with said plunger and the valves in the passage-ways leading from the air-pump cylinders, and with said metal-controlling valve, and which actuate the same in the following order during the exhausting movement of the pistons, namely: first the valve in one of said passage-ways to open the same, then this valve and the valve in another of the passage-ways to close the first valve before opening the second, and finally the plunger and the metal-controlling valve to admit molten metal under pressure into the mold.

8. In a casting-machine, the combination with a plunger for subjecting molten metal to pressure, a mold, and an air-valve for admitting air at a predetermined time to the mold, of a plurality of air-pumps communicating with the mold for producing a vacuum therein; valves controlling the passage-ways leading from the air-pump cylinders to the mold; a valve for controlling the entrance to the exhausted mold of molten metal; a main shaft from which the pistons of said air-pump cylinders are actuated; and a series of cams operatively connected to the shaft, and with said plunger and the valves in the passage-ways leading from the air-pump cylinders, and with said metal-controlling valve, and which actuate the same in the following order during the exhausting movement of the pistons, namely: first the valve in one of said passage-ways to open the same, then this valve and a valve in another of the passage-ways to close the first valve before opening the second, then the plunger and the metal-controlling valve to admit molten metal under pressure into the mold, and finally the air-valve to admit air into the mold.

9. In a casting-machine, the combination with a separable mold, of means for first producing a vacuum in the mold; means for next causing the filling of the mold with molten metal; means for afterward admitting air to the mold; means for finally separating the mold; and mechanism for causing the operation of the several means in the order specified.

10. In a casting-machine, the combination with a separable mold, of a plurality of separate means for producing a vacuum; means for causing the filling of the mold with molten metal; means for admitting air to the mold; means for separating the mold; and mechanism operatively connected to the machine for actuating the above means in the following order, to wit: to first render one of said vacuum-producing means effective to exhaust air from the mold, then to connect the partially-exhausted mold with a second vacuum-producing means, then to cause the injection into the mold of molten metal, then to admit air to the mold, and finally to separate the mold.

11. In a casting-machine, the combination with a separable mold, of a plurality of separate means embodying a pair of air-pumps for producing a vacuum; means for causing the filling of the mold with the molten metal; means for admitting air to the mold; means for separating the mold; and mechanism operatively connected to the machine for actuating the above means in the following order, to wit: to first render one of said air-pumps effective to exhaust air from the mold, then to connect the partially-exhausted mold with the other air-pump, then to cause the injection into the mold of molten metal, then to admit air to the mold, and finally to separate the mold.

12. In a casting-machine, the combination with a mold and with mold-filling means, of an air-pump embodying a main poppet-valve controlling communication between the pump-cylinder and the mold, and an auxiliary valve carried by the main valve and controlling communication between the mold and the outer air.

13. In a casting-machine, the combination with a mold and with mold-filling means, of an air-pump; a main valve controlling communication between the pump-cylinder and the mold; an auxiliary valve carried by the main valve and controlling communication between the mold and the outer air; and a valve-actuating mechanism for operating the main and auxiliary valves with relation to each other.

14. In a casting-machine, the combination with a shiftable mold having mold-sections adapted to move toward and away from each other transversely to the plane of their surface of contact and provided with a groove intersecting said surface, of a nozzle through which molten metal is injected into the mold; means for moving the mold into a casting position in contact with said nozzle and for withdrawing it therefrom; mechanism for separating the mold-sections upon the filling of the mold and after its withdrawal from its casting position; an air-pump cylinder and a flexible connection extending between the mold and the air-pump cylinder and communicating with said groove.

15. In a casting-machine, the combination with a mold having mold-sections adapted to move toward and away from each other transversely to their surface of contact and provided with a groove intersecting said surface, of mechanism for separating the mold-sections upon the filling of the mold, a conduit communicating with the groove through which air is exhausted from the mold; a valve for controlling the admission of air to the groove; means for applying a pressure to molten metal in the machine to effect its forcible injection into the exhausted mold; and mechanism for operating said valve to admit air into the mold after the injection of the metal thereto.

16. In a casting-machine, the combination with a discharge-nozzle, and an air-pump cylinder, of a mold shiftable relatively to the cylinder and to the discharge-nozzle; means for guiding the mold, and for advancing the same into a casting position in which it contacts with said nozzle, and for withdrawing it from such position; a flexible connection extending between the mold and the air-pump cylinder; and mechanism operatively connected to the machine which first causes the advance of the mold toward the nozzle, then the exhaustion of the mold, and finally the injection of molten metal into the exhausted mold.

17. In a casting-machine, the combination with a discharge-nozzle, and an air-pump cylinder, of a mold shiftable relatively to the cylinder and to the discharge-nozzle; means for guiding the mold in its movements, and for advancing the same into a casting position in which it contacts with said nozzle, and for withdrawing it from such position; an air-admission valve; a flexible connection extending between the mold and the air-pump cylinder; and mechanism operatively connected to the machine which first causes the advance of the mold toward the nozzle, then the exhaustion of the mold, then the injection of molten metal into the exhausted mold, and finally the admission of air to the mold subsequent to the injection of metal thereto.

18. In a casting-machine, the combination with a discharge-nozzle, and an air-pump cylinder, of a sectional mold shiftable relatively to the cylinder and to the discharge-nozzle; means for guiding the mold, and for advancing the same into a casting position in which it contacts with said nozzle, and for withdrawing it from such position; a flexible connection extending between the mold and the air-pump cylinder; and mechanism operatively connected to the machine which first causes the advance of the mold toward the nozzle, then the exhaustion of the mold, then the

injection of molten metal into the exhausted mold, and finally the withdrawal of the mold from the nozzle, and its separation.

19. In a casting-machine, the combination with a discharge-nozzle, and an air-pump cylinder, of a sectional mold shiftable relatively to the cylinder and to the discharge-nozzle; means for guiding the mold in its movements, and for advancing the same into a casting position in which it contacts with said nozzle, and for withdrawing it from such position; an air-admission valve; a flexible connection extending between the mold and the air-pump cylinder; and mechanism operatively connected to the machine which first causes the advance of the mold toward the nozzle, then the exhaustion of the mold, then the injection of molten metal into the exhausted mold, then the admission of air to the mold subsequent to the injection of metal thereto, and finally the withdrawal of the mold from the nozzle, and its separation.

20. In a casting-machine, the combination with a discharge-nozzle, and a pair of air-pump cylinders, of a sectional mold shiftable relatively to the cylinders and to the discharge-nozzle; means for guiding the mold in its movements, and for advancing the same into a casting position in which it contacts with said nozzle, and for withdrawing it from such position; an air-admission valve; flexible connections extending between the mold and the air-pump cylinders; and mechanism operatively connected to the machine which first causes the advance of the mold toward the nozzle, then the exhaustion of the mold, then the admission of air to the mold subsequent to the injection of metal thereto, and finally the withdrawal of the mold from the nozzle, and its separation.

21. In a casting-machine, the combination with a discharge-nozzle and an air-pump cylinder, of a sectional mold shiftable relatively to said cylinder; means for guiding the mold in its movements and for advancing the same into a casting position in which it contacts with said nozzle and for withdrawing it from such position; an air-admission valve for said cylinder; means for positively operating said valve; means for separating the sections of the mold from each other; and a flexible connection extending between and connecting the air-pump cylinder with the mold.

22. In a casting-machine, the combination with a discharge-nozzle, and an air-pump cylinder, of a sectional mold shiftable relatively to said cylinder; means for guiding the mold in its movements, and for advancing the same into a casting position in which it contacts with said nozzle, and for withdrawing it from such position; a main valve for admitting air from the mold to the air-pump cylinder; an air-admission valve carried by the main valve for admitting air to the mold before its withdrawal and separation; and a flexible connection extending between and connecting the air-pump cylinder with the mold.

23. In a casting-machine, the combination with a discharge-nozzle, and two air-pump cylinders, of a sectional mold shiftable relatively to said cylinders; means for guiding the mold in its movements, and for advancing the same into a casting position in which it contacts with said nozzle, and for withdrawing it from such position; an air-admission valve; flexible connections extending between and connecting the air-pump cylinders with the mold; and mechanism operatively connected to the machine which first causes the advance of the mold toward the nozzle, then the exhaustion of the mold, then the admission of air to the mold subsequent to the injection of metal thereto, and finally the withdrawal of the mold from the nozzle, and the separation of its sections one from the other.

24. In a casting-machine, the combination with a mold; means for subjecting molten metal to a pressure greater than atmospheric; means for holding the metal and permitting it to flow, in consequence of such pressure, in a direction other than into the mold; and a plurality of air-pumps for producing a vacuum in the mold, of means for shifting the direction of flow of the molten metal; a power-driven device in the machine; and mechanism operatively connected with said device which renders one of the air-pumps effective to partially exhaust the mold, said pressure means effective to establish the flow in the metal and the operating-pump subsequently ineffective and a second pump effective to further exhaust the partially-exhausted mold; and then, subsequent to the establishment of the flow, causes the means for shifting the direction of such movement, thereby effecting the diversion of the flow toward and into the mold.

25. In a casting-machine, the combination with a melting-tank and a chamber connected to the tank and normally shut off from communication with the mold, of means for subjecting a mass of molten metal communicating with that in the chamber to a pressure greater than atmospheric and thereby set up a movement in the body of metal in the chamber outward into the tank; means for suddenly opening communication between the chamber and the mold and for simultaneously arresting the flow of metal from the chamber into the tank; a plurality of air-pumps for producing a vacuum in the mold; a power-driven device in the machine; and mechanism operatively connected with said device which renders one of the air-pumps effective to partially exhaust the mold, said pressure means effective to establish the flow of the metal in the chamber and the operating-pump subsequently ineffective and a second

pump effective to further exhaust the partially-exhausted mold; and then, subsequent to the establishment of such flow, causes the means for opening communication between the chamber and the mold and simultaneously arresting the flow of metal in other directions, thereby diverting the direction of flow toward and into the mold.

26. In a casting-machine, the combination with a melting-tank, a mold and a chamber in normal communication with the tank, of means for subjecting a mass of molten metal communicating with that in the chamber to a pressure greater than atmospheric and thereby set up a movement in the body of metal in the chamber outward into the tank; a valve for closing communication between the chamber and the tank; a valve for controlling the inlet of molten metal to the mold from the chamber; a plurality of air-pumps for producing a vacuum in the mold; a power-driven device in the machine; and mechanism operatively connected with said device which renders one of the air-pumps effective to partially exhaust the mold, said pressure means effective to establish the flow of the metal in the chamber, and the operating-pump subsequently ineffective and a second pump effective to further exhaust the partially-exhausted mold; and then, subsequent to the establishment of such flow, causes said valve to thereby close communication between the chamber and the tank and simultaneously open communication between the chamber and the mold.

27. In a casting-machine, the combination with a melting-tank; a mold and a chamber in normal communication with the tank, of means for subjecting a mass of molten metal communicating with that in the chamber to a pressure greater than atmospheric and thereby set up a movement in the body of metal in the chamber outward into the tank; a double-action valve for controlling communication between the chamber and the mold and the chamber and the tank; a plurality of air-pumps for producing a vacuum in the mold; a power-driven device in the machine; and mechanism operatively connected with said device which renders one of the air-pumps effective to partially exhaust the mold, said pressure means effective to establish the flow of the metal in the chamber, and the operating-pump subsequently ineffective and a second pump effective to further exhaust the partially-exhausted mold; and then, subsequent to the establishment of such flow, causes said valve to thereby simultaneously close communication between the chamber and the tank and open communication between the chamber and the mold.

28. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric; means for holding the metal and permitting it to flow in consequence of such pressure in a direction other than into the mold; a nozzle; a shiftable mold; means for shifting the mold toward and away from the nozzle; and a plurality of air-pumps for producing a vacuum in the mold, of means for shifting the direction of flow of the molten metal and diverting the same toward and into the mold; a power-driven device in the machine; and mechanism operatively connected with said device which first actuates the means for shifting the mold toward the nozzle; then renders one of the air-pumps effective to partially exhaust the mold, said pressure means effective to establish the flow of the metal and the operating-pump subsequently ineffective and a second pump effective to further exhaust the partially-exhausted mold; and then, subsequent to the establishment of the flow, causes the means for shifting the direction thereof, thereby diverting the flow toward and into the mold.

29. In a casting-machine, the combination with a melting-tank; a nozzle; a shiftable mold; a chamber connected to the tank and normally cut off from communication with the mold; means for shifting the mold toward and away from the nozzle; and a plurality of air-pumps, of means for subjecting a mass of molten metal communicating with that in the chamber to a pressure greater than atmospheric and thereby set up a movement of the body of metal in the chamber outward into the tank; means for suddenly opening communication between the chamber and the mold and for simultaneously arresting the flow of metal into the tank; a power-driven device in the machine; and mechanism operatively connected with said device which first actuates the means for shifting the mold toward the nozzle; then renders one of the air-pumps effective to partially exhaust the mold, said pressure means effective to establish the flow of the metal in the chamber and the operating-pump subsequently ineffective and a second pump effective to further exhaust the partially-exhausted mold; and then, subsequent to the establishment of the flow, causes the means for opening communication between the chamber and the mold and simultaneously arresting the flow of metal into the tank, thereby diverting the flow toward and into the mold.

30. In a casting-machine, the combination with a mold having a passage-way in its body for a chilling liquid; means for subjecting molten metal to a pressure greater than atmospheric; means for holding the metal and permitting it to flow in consequence of such pressure in a direction other than into the mold; and a plurality of air-pumps for producing a vacuum in the mold, of means for shifting the direction of flow of the molten metal; a power-driven device in the machine; and mechanism op-

eratively connected with said device which renders one of the air-pumps effective to partially exhaust the mold, said pressure means effective to establish the flow in the metal and the operating-pump subsequently ineffective and a second pump effective to further exhaust the partially-exhausted mold; and then, subsequent to the establishment of the flow, causes the means for shifting the direction of such movement, thereby effecting the diversion of the flow toward and into the mold.

31. In a casting-machine, the combination with means for subjecting a mass of molten metal to a pressure greater than atmospheric; means for holding the metal and permitting it to flow, in consequence of such pressure, in a direction other than into the mold; a nozzle; a shiftable mold having a passage-way in its body for a chilling liquid; means for shifting the mold toward and away from the nozzle; and a plurality of air-pumps for producing a vacuum in the mold, of means for shifting the direction of flow of the molten metal and diverting the same toward and into the mold; a power-driven device in the machine; and mechanism operatively connected with said device which first actuates the means for shifting the mold toward the nozzle; then renders one of the air-pumps effective to partially exhaust the mold, said pressure means effective to establish the flow of the metal and the operating-pump subsequently ineffective and a second pump effective to further exhaust the partially-exhausted mold; and then, subsequent to the establishment of the flow, causes the means for shifting the direction thereof, thereby diverting the flow toward and into the mold.

32. In a casting-machine, the combination with a separable mold embodying a part of mold-sections of mold-filling means having a discharge-nozzle operatively connected with the machine for supplying molten metal to the mold; and mechanism operatively connected to the machine for shifting said mold-sections different distances in a common path relatively to each other toward and from said opening and into and out of operative relation with the mold-filling means.

33. In a casting-machine, the combination with a discharge-nozzle; a reciprocating mold embodying mold-sections separable from one another and movable different distances relatively to the discharge-nozzle, of a plurality of air-pumps for producing a vacuum in the mold; means for forcibly injecting molten metal thereto; a power-driven device in the machine; and mechanism operatively connected with said device which first shifts the mold into contact with said discharge-nozzle and closes the mold-sections, then renders one of the air-pumps effective to partially exhaust the mold and subsequently ineffective and a second pump effective to further exhaust the partially-exhausted mold, then renders the means effective for forcibly injecting molten metal into the mold, and finally, shifts the mold out of contact with the discharge-nozzle and separates the mold-sections.

34. In a casting-machine, the combination with a separable mold embodying a pair of mold-sections co-operative for forming a casting, of mold-filling means having a discharge-opening for supplying molten metal to the mold, and power mechanism for shifting said mold-sections different distances in the same direction relatively to each other to effect the opening and closing of the mold.

35. In a casting-machine, the combination with a sectional mold, of a carrier for each mold-section; carrier-actuating mechanism for shifting the carriers and separating the mold-sections from each other; a casting-stripper pivotally connected at different points of its length to one of said sections and to a member relatively to which said sections move when actuated, said stripper being disposed in the plane of movement of the section in which it is pivotally connected and having its pivotal axis extending transversely to the plane of movement of such section, whereby the stripper is caused to swing transversely to the apex of the casting.

36. In a casting-machine, the combination with a nozzle through which molten metal is injected into the mold, of a sectional mold, and mechanism for shifting the mold-sections as a unit away from the nozzle, and then stopping the movement of one mold-section and continuing the movement of another section in the line of retracting movement of the mold.

37. A method of casting a plurality of mold-sections, in combination with a main carrier upon which the mold is mounted, one of the mold-sections being mounted upon said main carrier and being adapted to move relatively thereto; a spring for urging the said relatively movable section into contact with its co-operative section; and a stop for limiting the motion of said relatively movable section at some time before the mold reaches the limit of its retracting movement.

38. A sectional mold in combination with a spring for urging the mold into its casting position; means for retracting it therefrom; a carrier upon which the mold is mounted, springs for urging the various mold-sections into a position in which they contact with each other; a stop for limiting the retracting movement of one of the sections; and means for separating the retracting mold-sections during the further retracting movement of the mold.

39. In a casting-machine, the combination with a separable mold

not with mold-section carriers adapted to be moved different distances in the same direction to close the mold, of a plurality of pressure-exerting means adapted to exert upon the mold-sections different pressures toward the mold-filling means to press the mold firmly in contact with the latter and to press the mold-sections together during the filling of the mold.

46. In a casing-machine, the combination with a movable mold, of mold-filling means comprising a plunger; a mold-carrier for each section; mold-carrier-operating means for closing said mold-sections; a spring-actuated locking-pawl operative for preventing the operation of the plunger until all of said mold-sections are in proper position; and a pawl-releasing device carried by the mold and effective to release the locking-pawl when the mold is in its proper position.

688,597. WRAPPER OR LABEL ASSEMBLING MACHINE. CLARENCE R. VOTAW, Indianapolis, Ind., assignor of one-half to Newton H. Kester, Indianapolis, Ind. Filed July 29, 1904. Serial No. 69,982

Claim.—1. In a machine of the character specified, the combination with a suitable frame, paper-feeding rollers and driving mechanism thereof, of a knife adapted to sever the continuous strip of paper into predetermined lengths and suitable expelling mechanism to receive the individual labels and deliver them into a receptacle according to a desired classification, a plurality of elements and electrical devices all substantially as described and for the purpose set forth.

2. In a machine of the character specified, a suitable frame, paper-feeding rollers and driving mechanism therefor, a sheet-chute and a plurality of stamens cooperating therewith; a knife adapted to sever and strip of paper into individual labels and conveying mechanism designed to pick up and convey each label to the first pair of rolls, and means for delivering the labels into a receptacle designed especially to receive the same, all substantially as specified and for the purpose set forth.

3. In a machine of the character specified, the combination with a suitable frame, of a sound-guiding channel; a direct-terminal carried by said channel, in combination with a stam having a frame fitting said channel, and provided with a metal rivet or the like; a lead magnet in said channel and a contact-head having a plurality of pins forming the other terminal of said circuit and means to cause the registration of an individual pin with its respective rivet whereby a circuit will be closed and said magnet energized, all combined as specified and for the purpose set forth.

4. In a label or wrapper covering machine, the combination with a suitable frame, a plurality of stems, and electrical devices of a paper-cutting blade; means to operate said blade and additional means to engage the individual label formed by the knife and convey the same to a receptacle designed to receive it so and for the purpose set forth.

5. In a label printing and mounting machine, a suitable frame; a plurality of stands; means to feed said strip of paper in engagement with each stand; a local magnet; a conveyor-chain; means to engage

each individual label or wrapper and additional means carried by the stencil-frame adapted to open and close an electric circuit, all combined as and for the purpose set forth.

9. In a wrapper or label printing and inserting machine, a suitable frame; a plurality of stencils of non-conducting material having an electric conducting portion; a guideway for said stencils; a contact-piece carried by said guideway; a movable contact-head having a plurality of circuit-terminals and means to cause the registration of an individual pie with the metallic part of said stencil-frame whereby an electric circuit will be closed and a local signal will be generated all combined substantially as specified and for the purpose set forth.

7. Is a machine of the character specified, a suitable means; paper-folding mechanism; a stencil-plate and a plurality of stencils and means to feed said stencils through said chain, in combination with additional means to press a part of said paper in engagement with an individual stencil; a contact-head having a plurality of circuit-terminals; means carried by the stencils to form an electric connection between said terminals and said contact-plate; suitable means to cover said strip of paper into suitable lengths and label-receiving devices designed to take each individual label and deliver the same within a receptacle especially designed to receive it, all substantially as specified and for the purpose set forth.

8. In a machine of the character specified, the combination with a suitable supporting-frame; of paper feeding and printing mechanism; a knife adapted to cover the paper into individual labels; means to operate said knife; label-carrying device; a plurality of compartments and suitable selecting mechanism cooperating with said label-carrying device adapted to open the door of the receptacle designed to receive a specified label; all combined as specified and for the purpose set forth.

9. In a label or wrapper frame; a plurality of electric coils provided with a door; a series of elements of non-conducting material having a metallic portion; a plurality of pins each forming the other terminal of the electric circuit and means to force an individual pin into engagement with the metal part of the element-frame whereby the circuit will be closed between said pin and said contact-plate and thereby energize said magnet and open a door in case of said receptacles to receive a specified label, all combined substantially as specified and for the purpose set forth.

10. In a machine of the character specified, a stencil-plate having a metallic contact-plate comprising one terminal of an electric circuit and a plurality of pins comprising the other terminals of the circuit, combined with a stencil having a frame of non-conducting material and provided with a metallic part and means to force said pins downward in engagement with said frame whereby one of said pins will be brought into registration with said metallic portion and thereby close one of the electric circuits represented by said pin and thus energize a magnet located therein all as claimed or specified and for the purpose set forth.

11. In a label-sorting machine, a suitable frame; a plurality of receptacles, each having a door, all of which when closed will form the floor of the machine; a plurality of steeple, a contact-plate and pins carried thereby and electrical connections; a plurality of local magnets; means to operatively connect said door with its individual magnet and means to close the circuit of the magnet controlling the door; of the receptacle designed to receive a specified label when said label approaches said door all combined substantially as specified and for the purpose set forth.

12. In a machine of the character specified, the combination with a suitable frame, paper-feeding rollers and driving mechanism thereof, of cooperating mechanism to receive the individual labels and automatically deliver them into a receptacle according to a desired classification, all substantially as specified and for the purpose set forth.

898,598. NEW-YORK-CENTINER GUARD. JOHN F. VRAZAKI.
Council Bluffs, Iowa. Filed June 26, 1901. Serial No. 66,421. (No
model)

Claim.—1. Is a neck-yoke-center guard, the combination with a pole-tip, of a guard comprising two curved hoops having openings at opposite sides near one end, and a pin extending from one of said openings to the other, as and for the purpose set forth.

2. A neck-yoke-collar guard, comprising an approximately oval member bent to conform to a cylinder, in combination with a pole-tip, said member being pivotally secured near one end to said pole-tip, as and for the purpose set forth.

698,599. MACHINE FOR FORMING BRICKS, TILE, etc. WILLIAM R. WAKEFIELD, Mount Union, Pa. Filed Oct. 20, 1901. Serial No. 39,490. (No model.)

Claim.—1. The combination with a suitable gearing, of a hopper arranged adjacent thereto, a plunger reciprocating in said hopper, a conveyor beneath the hopper and meshed thereby, said plunger being adapted to be actuated by the gearing, a second plunger arranged near the first plunger, and a smoothing-travel, adapted to be reciprocated over the top of the mold.

2. The combination with a gearing, of the conveyor arranged beneath the same, molds traveling on said conveyor, a hopper arranged above the same, a plunger working in said hopper adapted to force material into the molds, and a finishing-travel arranged by the gearing adapted to pass over the molds to give a finished appearance to the molded articles.

3. The combination with a horizontally-arranged conveyor and mold carried thereby, of a hopper arranged above the conveyor, means for feeding material from the hopper into the mold, means for packing the material after the mold leaves the hopper, and a spring-pressed laterally-moving device for smoothing off the top of the material within the mold.

4. The combination with the conveyor and mangle carried thereby, of a feed device arranged above the mangle and adapted to fill the same, a resiliently-mounted packing device positioned above the conveyor and adapted to pack the material within the mangle, and an adjustable finishing-trowel arranged adjacent the packing-plunger and adapted to bear upon and underlie over the top edges of the mold.

5. The combination with a conveyor consisting of links, the alternate links of which are provided with cut-out portions, of a mold adapted to be carried by said conveyor, oppositely-disposed lips or projections on the outer walls of said mold and adapted to engage the cut-out portions of the links, means for filling the mold arranged above the conveyor, and a resilient smoothing device adapted to reciprocate and bear upon the top edges of the mold.

6. The combination with a conveyor comprising chains, the alternate links of which are provided with cut-out portions, a mold adapted to be carried by said conveyor, legs or projections on the mold adapted to engage the cut-out portions of the links whereby the mold will be released at the end of the conveyor, and means for packing material within the mold.

7. The combination with a conveyor and a mold carried thereby, of means for packing material into the mold, and a reciprocating spring-pressed finishing-trowel adapted to reciprocate over the top of the mold after the material has been packed therein.

3. The combination with a conveyor and a mold carried thereby, a feed mechanism arranged above the conveyor and adapted to feed material into the mold, a packing-plunger arranged adjacent the feed mechanism and a finishing device arranged adjacent the packing-plunger, and a gearing connected to the feed mechanism, packing-plunger and finishing device.

9. The combination with a conveyor and a removable mold carried thereby, a feeding device above the mold, a packing-plunger arranged adjacent thereto and adjustably supported above the conveyor and the spring-pressed and adjustable finishing device adapted to bear upon the top of the mold and retractable thereon.

10. The combination with a conveyor, of a mold carried thereby, a hopper arranged above the mold, a resiliently-mounted plunger reciprocating in the hopper and adapted to feed material into the mold, means for pushing material into the mold and an adjustable spring-pressed and reciprocating finishing device adapted to bear upon the top of the mold for the purpose described.

11. The combination with a conveyor and a mold carried thereby, of a feed device arranged above the mold and adapted to fill the same, means for packing the material into the mold and an adjustable spring-pressed finishing device adapted to reciprocate and bear upon the top of the mold as it is moved by the conveyor.

12. The combination with a mold, a feed device adapted to empty into the mold and a spring-pressed finishing device adapted to move laterally over the top of the mold, and means for moving the mold from the feed device to the finishing device.

13. The combination with a gearing, of a conveyor, a mold carried thereby, a feed device for the mold, a packing device, a finishing device, and means for throwing the conveyor out of operation with relation to the remaining parts.

14. The combination with a gearing, of a conveyor, a mold carried thereby, a feed device for the mold, a packing device, a finishing device, and means for throwing the packing device out of operation without affecting the operation of the remaining parts of the machine.

15. The combination with a conveyor and mold carried thereby, a feed device arranged to empty into the mold, a pushing device and a finishing device, supporting-base for the finishing device provided with elongated slots, means on the finishing device for engaging the elongated slots and means for repositioning the finishing device laterally within the slots.

18. The combination with a conveyor and a mold carried thereby, means for depositing material into the mold, means for packing it, a finishing device adapted to move over the mold, supporting-bars provided with elongated slots in which the finishing device is adapted to reciprocate, a bar positioned above the supporting-bars and a spring carried by the last-mentioned bar and bearing upon the supporting-bars.

17. The combination with a conveyor and a mold carried thereby, means for depositing material into the mold, means for packing it, a finishing device adapted to reciprocate over the mold, vertical standards, supporting-bear vertically movable on said standards and supporting the finishing device, an adjustable bar above the supporting-bear, and a spring carried thereby and bearing on the supporting-bear.

698,600. DOCUMENT-ENVELOP. JOHN C. WALLACE, Chicago, Ill., assignor of one-half to John E. Morgan, Chicago, Ill. Filed Nov. 25, 1921. Serial No. 92,557. (No model.)

Chain.—1. The herein-described document-envelop comprising the folded bottom and ends hinged together, the pairs of inner side walls E, H, and F, G, hinged to the folded ends A respectively and the outer side walls C, D hinged to the folded bottom, the outer side wall D having a division line D' substantially as described.

2. The herein-described document-envelope comprising the folded bottom and ends A hinged together, the inner side walls E, H, hinged to one side of the folded ends A respectively and overlapping each other for approximately the full length of the envelope, the inner side walls F, G, hinged to the other side of the folded ends A respectively and similarly overlapping each other, and the outer side walls G, D, hinged to the folded bottom, the latter of which has a hinged closing-flap D'; substantially as described.

2. The herein-described document-envelope comprising: the folded bottom and ends A hinged together, a main side wall hinged to the bottom at one side of the envelope and having a hinged closing-flap, the inner side walls B, H, hinged to the ends A at the opposite side of the envelope, and the outer side wall C hinged to the bottom and provided

with the extension-flap C' folded inward over the top edge of said inner side wall; substantially as described.

6. The herein-described document-envelope comprising the folded bottom and ends A' hinged together, suitable inner side walls hinged to the ends respectively, outer side walls hinged to the bottom, one of which outer side walls has a hinged closing-flap and strengthening-ribs I integral with the upper ends of the folds of the ends A' and folded over upon and secured to each end; substantially as described.

7. The herein-described document-envelope comprising the bottom and ends A, the latter provided in their upper edges with the integral strengthening-ribs I, the inner side walls F, G, at one side of the envelope, the outer side wall D secured thereto, and provided with the hinged closing-flap D', the inner side walls H, I, at the opposite side of the envelope and the outer side wall C secured thereto and provided with the extension-flap C' bent inward over the upper edge of said side walls and secured to the inner flaps thereof; substantially as described.

8. The herein-described blank for a document-envelope comprising a bottom and ends hinged together and provided with a series of plates or hollow folds A extending longitudinally thereof from end to end, the inner side walls E, F, G, H, hinged to the ends respectively, and the outer side walls O, D, hinged to opposite sides of the bottom, and separated from the inner side walls by the transverse cuts B terminating at the folds of the bottom, and said folds having transverse creases F' in line with said cuts and angular creases B' at the inner sides of the transverse creases, and the closing-flap D' hinged to the side wall D; substantially as described.

9. The herein-described blank for a document-envelope, substantially rectangular in shape and comprising the inner side walls E, F, G, H, and the outer side walls O, D, separated therefrom by the cuts B and having the extensions C', D' and the series of longitudinal folds A connecting the side walls of the opposite sides of the blank; substantially as described.

10. The herein-described blank for a document-envelope, substantially rectangular in shape and comprising the inner side walls E, F, G, H, and the outer side walls O, D, separated therefrom by cuts B and having the extensions C' D' and the series of longitudinal folds A connecting the side walls of the opposite sides of the blank; and provided at their extremities with the strips I; substantially as described.

698,601. COMBINATION-TOOL. JAMES WEAVER, Indianapolis, Ind., assignor of one-half to John A. Robbins, Indianapolis, Ind. Filed Nov. 25, 1901. Serial No. 53,812. (No model.)

Claim.—1. In a combination-tool, a base comprising a pair of iron bars held parallel by end blocks, a head having parallel flanges between which said base is removably secured, said head having a sliding jaw, a shaft removably secured to the jaw, a screw having a longitudinal bore in which said shaft is mounted, said screw being held in a threaded portion of the head, a second block having a lever portion making sliding fit between the base of the base and having its upper portion formed into a vise-jaw to mate with the sliding jaw, the lower portion of said block having a projecting portion with top indentations and a pin passing through the base of the base and engaging one of the said indentations to prevent the longitudinal movement of the second block.

2. In a combination-tool, a base comprising a pair of flat iron bars turned edge up and held parallel by end blocks to which the bars are bolted, said bars having a plurality of holes to opposite sides, a head having a pair of parallel flanges between which the base is removably secured, a horizontal plate on said head, a sliding jaw mounted thereon and having lugs to engage the edges of the plate, an extension of the head above the plate having a screw-threaded bore longitudinally of the head, a threaded sleeve covering in said bore said screw having a longitudinal bore and having a head-wheel at one end, a shaft seated in the bore of the sleeve having a removable transverse pin to secure the sliding jaw to the shaft, a block seated between the base of the base having side flanges resting on the base, a projecting portion tapering toward its outer end having top indentations to engage a screw-pin, a screw-pin is a pair of the holes of the base to engage the indentations of said block extension, the upper portion of said block being formed to act as a vise-jaw to mate with the sliding jaw.

3. The combination of a pair of parallel bars, a screw-shaft carried by a fixed member thereof, a screw-shaft carried by said head-block to move a vise-head or a drill longitudinally of said bars, and a tail-block seated between the bars and extending up to form a bearing for the vise or drill and having a projecting portion with top indentations and a pin passing

through said bars and engaging one of said indentations to prevent longitudinal movement of said tail-block.

698,602. PHOTOGRAPHIC REPRODUCER. FRANK WILSON, West Orange, N. J. Filed Feb. 8, 1901. Serial No. 46,176. (No model.)

Claim.—1. In a photographic reproducing device, the combination of a disk-like body, a compensating weight movable vertically with respect to the same, a diaphragm carried by and bodily movable with said weight, an auxiliary lever universally pivoted to the compensating weight, and a reproducing device carried by said lever and connected to the diaphragm, substantially as set forth.

2. In a photographic reproducing device, the combination of a disk-like body, a compensating weight movable vertically with respect to the same, a diaphragm carried by and bodily movable with said weight, an auxiliary lever universally pivoted to the compensating weight, a reproducing device carried by said lever and connected to the diaphragm, and a yoke for limiting the downward movement of said lever, substantially as set forth.

3. In a photographic reproducing device, the combination of a disk-like body having an integral neck, a tube vertically movable in said neck, a compensating weight carried by said tube within the body, a diaphragm carried by and bodily movable with the compensating weight, an auxiliary lever universally pivoted to said compensating weight beneath the diaphragm, and a reproducing device pivoted to said lever and connected to the diaphragm, substantially as set forth.

4. In a photographic reproducing device, the combination of a disk-like body having an integral neck, a tube vertically movable in said neck, a compensating weight carried by said tube within the body, a diaphragm carried by and bodily movable with the compensating weight, an auxiliary lever pivoted to said compensating weight beneath the diaphragm and capable of lateral movement with respect thereto, a reproducing device pivoted to said lever and connected to the diaphragm, an anti-friction-roller interposed between the free end of said lever and the compensating weight, substantially as set forth.

5. In a photographic reproducing device, the combination of a disk-like body having an integral neck, a tube vertically movable in said neck, a compensating weight carried by said tube within the body, a diaphragm carried by and bodily movable with the compensating weight, an auxiliary lever pivoted to said compensating weight beneath the diaphragm and capable of lateral movement with respect thereto, a reproducing device pivoted to said lever and connected to the diaphragm, an anti-friction-roller interposed between the free end of said lever and the compensating weight, and a yoke for limiting the downward and lateral movements of said lever, substantially as set forth.

698,603. BOOK. THOMAS E. WILSON, JR., Philadelphia, Pa. Filed Jan. 12, 1902. Serial No. 50,207. (No model.)

Claim.—1. A book or pamphlet comprising a plurality of main leaves, each consisting of a main portion and an outer foldable section, and a plurality of inner leaves, the length of the main portions of said main leaves being approximately a multiple of the length of said sections and of said inner leaves.

2. A book or pamphlet consisting of a plurality of leaves, each leaf consisting of a main portion and an outer foldable section, the latter being

approximately half the length of the former, and a plurality of inner leaves of approximately the length of said sections.

3. A book or pamphlet comprising a plurality of main leaves, each consisting of a main portion and an outer foldable section, and a plurality of inner leaves, the length of the main portions of the book leaves being approximately a multiple of the length of said sections and of said inner leaves, said main portions of the book leaves being provided with complete pictures, and said sections and inner leaves being provided with interchangeable sections of pictures.

4. A book or pamphlet comprising a plurality of main leaves, each consisting of a main portion and an outer foldable section, and a plurality of inner leaves, the length of the main portions of the book leaves being approximately a multiple of the length of said sections and of said inner leaves, said main portions being provided with pictures, and said sections and inner leaves being provided with sections of pictures interchangeable with each other and with the pictures of the main portions.

5. A book or pamphlet consisting of a plurality of main leaves, each leaf consisting of a main portion and an outer section foldable upon both sides of said main portion, and a plurality of inner leaves foldable upon both sides of said main portion, the length of the main portions of said book leaves being a multiple of the length of said sections and of said inner leaves, said main portions being provided with pictures on opposite sides thereof, and said sections and inner leaves being provided with interchangeable sections of pictures on opposite sides thereof.

6. A book or pamphlet consisting of a plurality of leaves, each leaf consisting of a main portion and an outer foldable section, the latter being approximately half the length of the former, and a plurality of inner leaves of approximately the length of said sections, said main portions being provided with a picture, and said sections and inner leaves being provided with interchangeable sections of pictures.

7. A book or pamphlet consisting of a plurality of leaves, each leaf consisting of a main portion and an outer section, foldable on both sides thereof, said outer section being approximately half the length of said main portion, a plurality of inner leaves approximately the same length as said sections and foldable upon both sides of said main portion, said main portions being provided with pictures on both sides thereof, and said sections and inner leaves being provided with interchangeable sections of pictures on both sides thereof.

698,604. WAGON END-GATE AND SHOVELING-BOARD. DAVID K. WILK, Lake City, Iowa. Filed Sept. 2, 1901. Serial No. 74,727. (No model.)

Claim.—1. The combination with a wagon and an end-gate having openings therein, of two arms fixed to the wagon-box to project rearwardly and having openings in their ends, and two arms pivotally connected with the wagon-box above the first-mentioned arms and also having openings in their ends, slide-bolts or the like on the rear end of the end-gate to pass through the openings in the ends of said arms to lock the end-gate to the wagon-box, and arms pivoted to the end-gate and adjustably connected with the wagon-box, for the purpose stated.

2. The combination with a wagon-box and an end-gate having openings therein, of two arms fixed to the wagon-box near its lower end to project rearwardly beyond the ends of the wagon-box and having openings in their ends, and two arms pivoted to the wagon-box above the first-mentioned arms to swing in a vertical plane and also having openings in their outer ends, and stops to limit the movement of these pivoted arms, slide-bolts secured to the rear surface of the end-gate to pass through the openings in said arms, and arms pivoted to the end-gate and adjustably connected with the wagon-box, for the purpose stated.

3. The combination with a wagon and an end-gate, of two arms fixed to the rear lower corners of the wagon-box and projected rearwardly, two arms pivoted to the rear upper corners of the wagon-box to swing in a vertical plane, means for detachably connecting the end-gate with the lower arms, and means for detachably connecting the end-gate with the upper arms, and two rods pivoted to the sides of the end-gate and adjustably connected with the sides of the wagon-box to be capable of supporting the end-gate in a horizontal position with its lower end engaging the

bottom portion of the wagon-bed and also capable of supporting the end-gate with its upper end in engagement with the pivotal arms on the wagon-bed, and its other end extended straight rearwardly, substantially as and for the purpose stated.

4. The combination with a wagon-box, of a cross-piece projecting rearwardly and laterally, uprights secured in the inner corners of the wagon box, arms pivoted to the upper portions of the uprights having openings in their free ends, stops for limiting the downward movement of these arms, arms fixed to the lower end of the uprights and projected rearwardly and having openings in their rear ends, lugs projecting laterally from the sides of the wagon-box, bolts secured to the wagon-box beneath the said lugs, on end-gates having side plates to overlap the said uprights and also having openings to receive the said bolts, two lugs secured to the rear corners of the end gate, slide-bolts pivoted to said lugs at opposite sides of their distal ends, guides for the slide-bolts, bolts to receive the ends of said lugs, stops secured to the sides of the end-gate designed to pass through the lugs on the wagon-box, arms pivoted to the said stops and having bolts at their ends, said arms being designed to pass through said bolts, and said bolts being designed to engage the lugs to support the end-gate in position for use as a churning-board, and said arms having notches therein to engage the lugs and support the end-gate in its elevated position, substantially as and for the purpose stated.

698,605. CONSTRUCTION OF STRUCTURES SUSTAINING CROSS STRAINS. HENRY WILSON, ALBANY, IOWA. Filed Jan. 24, 1902. Serial No. 51,130. (No model.)

Claim.—As a new article of manufacture, a composite structure of angle-iron and wood, the angle-iron being substantially cross-shaped in cross-section, and tapered endwise, and attached filling-strips of wood secured in the interspaces between the flanges as by rivets passing through the opposite wood strips and through holes in the angle-iron at the junction of its flanges, substantially as and for the purpose set forth.

698,606. RAIL-JOINT. CHARLES R. WILSON, Meyersdale, Pa. Filed Jan. 15, 1902. Serial No. 50,590. (No model.)

Claim.—1. In a rail-joint, the combination with the rails, fish-plates carrying a base portion and outwardly-extending flanges having guide-ways formed therein, securing-plates extending through said guide-ways and rails, and means whereby said fish-plates and securing-plates are secured to the cross-ties, substantially as described.

2. In a rail-joint, the combination with the rails, fish-plates carrying outwardly-extending base portions, an outwardly-extending flange secured to said base portion, guide-ways formed in said base portion, securing-plates extending through said guides and through the webs of the rails, means to secure said flanges to the ties, and means to secure said securing-plates to the base and ties, all parts being arranged and operating substantially as described.

698,607. APPARATUS FOR PRODUCING COMBUSTION. LEONARD S. WILK, Geneva, N. Y. Filed Feb. 3, 1901. Serial No. 46,799. (No model.)

Claim.—1. In combination with a combustion-chamber, an air-heating device having an air-heating chamber provided with inlet and discharge openings and with concentric ribs for forming an air-channel, a second rib extending across the channel, said inlet and outlet openings communicating with the channel at opposite sides of the second rib.

2. In combination with a combustion-chamber, an air-heating chamber having an inner heating wall and separated upper and lower walls formed respectively with inlet and outlet openings, a concentric partition

or rib within the annular wall and provided with an opening in one side, and a transverse rib dividing the space within the annular partition, the spaces at opposite sides of the rib being connected respectively to the inlet and outlet openings for causing the air to travel around the annular rib from the inlet to the outlet openings.

3. An air-heating device comprising a shell having a central plate and air-heating chambers at opposite sides of the plate and communicating with each other, said shell having an inlet-opening in one end leading to one of the chambers and an outlet-opening extending through the opposite end wall of the other chamber for the purpose described.

698,608. CENTERING-MACHINE. LOUIS R. WYATT, New London, Conn. Filed Mar. 7, 1900. Serial No. 708,145. (No model.)

Claim.—1. In combination, drilling mechanism, consisting of a laterally-movable head carrying two or more revolving and sliding spindles, means substantially as specified for sliding said spindles, means for supporting the rod to be centered consisting of a fixed chuck and a revoluble chuck, a swinging support for said revoluble chuck as set forth, and mechanism for simultaneously revolving the said spindles and the said rod.

2. In combination, a machine-bed, a slider mounted on the said bed and formed with lateral extensions 34', sleeves 39 41 located within said extensions, a splined shaft supported within and by the sleeve 39, a work-holding chuck mounted on the slider and formed with an extension 43' that is hinged on the sleeve 41 substantially as specified.

3. In combination, a machine-bed, a slider mounted on the said bed and formed with one or more lateral extensions 34', a sleeve 39 provided with gear 39' and key 40 located within said lateral extension, a splined shaft supported within and by the sleeve 39, a work-holding-chuck bearing 43' mounted on the slider and formed with an extension 43' that is hinged on the said sleeve, and a work-holding chuck revolvably mounted within the chuck-bearing 43' and provided with a gear 43'' which is adapted to coast with the gear 39' substantially as specified.

4. In combination, a machine-bed, a slider mounted on the said bed and formed with one or more lateral extensions 34', a sleeve 39 provided with gear 39' and key 40 located within said lateral extension, a splined shaft supported within and by the sleeve 39, a work-holding-chuck bearing 43' mounted on the slider and formed with an extension 43' that is hinged on the said sleeve, and a work-holding chuck revolvably mounted within the chuck-bearing 43' and provided with a gear 43'' which is adapted to coast with the gear 39' substantially as specified.

698,609. SPEED-REGULATOR. HERBERT T. WILSON, Rochester, Mass. Filed July 26, 1901. Serial No. 68,609. (No model.)

Claim.—1. The combination, with a driving-shaft provided with a crank, of a slidable cross-head provided with a screw-threaded socket, adjustable link mechanism connecting the said crank and cross-head and permitting the stroke of the cross-head to be varied, an oscillatory screw-threaded shaft operated by the said socket, a beveled toothed wheel secured on the said shaft, a power-shaft, beveled toothed wheels mounted on the said power-shaft and gearing into the said beveled toothed wheel on opposite sides thereof, and clutches between the said beveled toothed wheels and the power-shaft whereby the said power-shaft is revolved continuously, substantially as set forth.

2. The combination, with a driving-shaft provided with two cranks set at an angle to each other, of slidable cross-heads provided with screw-threaded sockets, link mechanisms connecting the said cross-heads and cranks, means for shifting the link mechanisms simultaneously to change the stroke of the cross-heads, oscillatory screw-threaded shafts operated by the said sockets, beveled toothed wheels secured upon the said shafts, a power-shaft, beveled toothed wheels mounted on opposite sides thereof, and clutches between the said pairs of beveled toothed wheels and the power-shaft whereby the said power-shaft is revolved continuously, substantially as set forth.

3. The combination, with a driving-shaft provided with a crank, of a slidable cross-head provided with a screw-threaded socket, a radius-rod

pivoted to the said shaft, a curved link pivoted at one end to the said radius-rod, a connecting-rod between the other end of the said link and the said crank, a block pivoted to the cross-head and engaging with the said link, means for shifting the said link so as to vary the stroke of the cross-head, and an oscillatory screw-threaded shaft operated by the said socket, substantially as set forth.

698,610. APPARATUS FOR MAKING STEEL. GEORGE C. WILSON, Phila. Pa. Filed Oct. 10, 1900. Serial No. 32,265. (No model.)

Claim.—1. The combination of a dome-section, a half-section independent thereof and adapted to coast therewith, and tapers in the half-section which tapers pass downwardly from a point in the upper surface of the half-section through the walls of the said dome-section and then turn and pass in a downward direction through the inner walls of the dome-section whereby the blast of air issuing from said tapers is directed upon the surface to be completed by the metal and toward the center thereof.

2. The combination of a dome-section, a half-section independent thereof and adapted to coast therewith, tapers in said dome-section and half-section, the tapers of said half-section extending downwardly from the upper edges thereof, through the walls of the said dome-section and then turning and passing in a downward direction through the inner walls of

the section and having their lower ends converging inwardly, whereby the blast from the said tapers is directed upon the surface to be completed by the metal and toward the center thereof, and blast-pipes leading to said tapers.

3. The combination of a cupola, a dome-section situated thereon, a half-section adapted to coast with said dome-section, and means for conducting metal from said cupola to said half-section.

4. As an improved article of manufacture, a half-section having therein tapers which pass downwardly from a point in the upper surface of the half-section through the walls thereof and then turn and pass downwardly through the inner walls whereby the blast of air will be directed upon the surface to be completed by the metal and toward the center thereof.

5. As an improved article of manufacture, a half-section having tapers in the walls thereof, projecting downwardly from the top of said section through the walls of the said section and then turning and passing in a downward direction through the inner walls of the section and converging inwardly and being adapted to conduct air into the interior of said section, upon the surface above the space to be occupied by the metal and toward the center thereof.

6. The combination of a cupola, a dome-section situated thereon, and a half-section arranged to coast with said dome-section.

7. The combination of a cupola, tapers thereon, a dome-section, supporting device for the latter, adapted to travel on said tapers, and a half-section arranged to coast with the said dome-section.

8. The combination of a cupola, a stack thereon, a smoke-head connecting with said stack and depending therefrom, a dome-section located below said smoke-head and rotatably mounted on the cupola and adapted to discharge therethrough, and a half-section arranged to coast with said dome-section.

9. The combination of a dome-section, a wind-box located at the lower portion thereof, an adjustable-mounted taper mounted in said section and wind-box, said taper being movable at its outer end from its lower end as a diater, a half-section having tapers therein, and means for conducting a blast to said tapers.

10. The combination of a cupola, a dome-section rotatably mounted thereon, and a half-section arranged to coast therewith.

11. The combination of a cupola, a dome-section movably mounted thereon, a half-section arranged to coast therewith and tapers for said half-section and dome-section.

12. The combination of a cupola, a dome-section movably mounted thereon, a half-section arranged to coast therewith, tapers for said half-section, and a series of adjustable tapers for said dome-section.

698,611. CARRIAGE OR WAGON SPRING. JOHN WILLIAMS, Swanton, England, assignor to John Ross, Swanton, England. Filed May 7, 1901. Serial No. 68,145. (No model.)

Claim.—In bushes for carriages and wagons the combination of the said cheeks a, plates b, distance-plates c, nuts d, and rivet pins or bolts e, constructed and arranged, substantially as described and for the purpose specified.

698,612. TELEPHONE WALL SET. CHARLES E. WYNN, Philadelphia, Pa. assignor to the Keytone Telephone Company Philadelphia, Pa., a Corporation of New Jersey. Filed July 20, 1901. Serial No. 68,771. (No model.)

Claim.—1. In a telephonic wall set, a bell-box having a movable lid at the top, fixed sides and a vertically-sliding front held in place by the lid when closed; a horizontally-sliding bottom held in place by the sliding front; and bell and ringing-coils mounted on the sliding bottom, substantially as described.

2. In a telephonic wall set, a bell-box having a movable lid at the top, fixed sides and a vertically-sliding front held in place by the lid when closed; a horizontally-sliding bottom held in place by the sliding front; a switch and a pivoted switch-controlling receiver-hook mounted on the sliding bottom; and a vertical slot reaching to the top of one of the sides through which the receiver-hook projects, substantially as described.

3. In a telephonic wall set, a bell-box having a sliding removable bottom; and a receiver made fast by the receiver-card to the sliding bottom, substantially as described.

4. In a telephonic wall set, a bell-box having a sliding removable bottom, to which the bell and ringing-coils, switch and receiver-hook, and also the connections of the receiver-card are attached, substantially as described.

5. In a telephonic wall set, a bell-box having a movable lid at the top, fixed sides and a vertically-sliding front held in place by the lid when closed; a horizontally-sliding bottom held in place by the sliding front; and bell, ringing-coils, induction-coil, switch and receiver-hook and receiver-card all made fast to the sliding bottom, substantially as described.

6. In a telephonic wall set, a bell-box having a movable lid at the top, fixed sides and a vertically-sliding front held in place by the lid when closed; a horizontally-sliding bottom held in place by the sliding front; bell and ringing-coils mounted on the sliding bottom; and means, under the control of the inductor, whereby the lid may be locked in place, substantially as described.

698,613. BASE-PLATE FOR TELEPHONE TRANSMITTER. ARTHUR CHAMBERLAIN E. WYNN, Philadelphia, Pa. assignor to the Keytone Telephone Company, Philadelphia, Pa., a Corporation of New Jersey. Filed July 20, 1901. Serial No. 68,772. (No model.)

Claim.—1. A transmitter-arm base-plate with a cavity underneath within which the terminal binding-curves are situated; an aperture in the face of the base-plate contiguous to the binding-curves; a covering for said aperture; and a screw by which the covering is secured to the aperture having an irregular head requiring a key to turn it, substantially as described.

2. A transmitter-arm base-plate with a cavity underneath within which the terminal binding-curves are situated; an aperture in the face of the base-plate contiguous to the binding-curves; a covering for said aperture which constitutes a number or instruction card for the transmitter; and means for fixing said covering over the aperture, substantially as described.

698,614. TYPE-WRITING AND ADDRESS MACHINE. JACOB C. WALSH, New York, N. Y. Filed Aug. 10, 1901. Serial No. 72,988. (No model.)

Claim.—1. The combination of a type-writing machine provided with a set of keys and type bearing the usual characters and a spacing-key, a traveling platen adapted to be moved step by step in its forward movement by the operation of each of said keys, a register or adding device adapted to be actuated by the numeral-keys of said set, traveling driving mechanism for said register connected with and operated by the mechanism for shifting the said platen and moving in response therewith, and means for preventing the shifting of the register-driving mechanism in response to the shifting platen when the penultimate or spacing key is operated to penultimate or space a printed number in its numeral order, substantially as and for the purpose set forth.

2. The combination of a register, driving mechanism for actuating said register and adapted to be shifted from one wheel to the other thereof, a series of numeral-keys for positioning and actuating said register-driving mechanism, means for printing the numeral character of each of the said keys as it is operated, spacing or penultimate mechanism for spacing or penultimate a line of printed figures in certain numeral order, and mechanism for holding at rest the register-driving mechanism when the said spacing or penultimate mechanism is actuated, substantially as and for the purpose set forth.

3. The combination of a register, driving mechanism for actuating any one of the register-number wheels and adapted to be shifted from one of said wheels to the other to actuate it, a series of numeral-keys for actuating said register and each connected with and controlling a type bearing its corresponding numeral character, a traveling platen against which said type print, connections between said numeral-keys and said platen for shifting the latter as each character is printed, connections between said shifting platen and said register-driving mechanism so that they are shifted together upon the operation of each key, spacing or penultimate mechanism for spacing or penultimate the line of printed figures in certain numeral order, and means for preventing the register-driving mechanism from shifting with the platen when the spacing or penultimate mechanism is actuated, substantially as and for the purpose set forth.

4. The combination of a register, a suitably-mounted shifting drive-wheel for actuating each of the register-number wheels and adapted to be shifted from one to the other of said wheels, a carriage for said drive-wheel, a series of numeral-keys and a series of corresponding type operated by said respective keys, a shifting platen against which the type set, connections between said platen and the drive-wheel carriage whereby the two may be shifted together upon the operation of each of said numeral-keys, spacing or penultimate mechanism for spacing or penultimate in certain numeral order the figures constituting a printed number and acting to shift the platen at each operation, connections between said platen and register-driving mechanism and means for shortening said connection a distance equal to one step of advance movement of the platen each time said spacing or penultimate mechanism is actuated and for lengthening said connection correspondingly upon the return movement of the platen, each means comprising the following parts, namely, a stationary toothed rack having at least the same number of teeth as the number of character-spaces to the line, a support moving in fixed relation with the shifting platen and provided with a movable toothed rack adapted to move in either direction of its length in the direction in which the platen travels, a suitable connection between said movable rack and the said register-driving mechanism, gearing arranged between the teeth of the two said racks in such relation that upon an advance movement of the platen said movable rack may be advanced likewise in fixed relation therewith a predetermined number of teeth, say three teeth, and then upon the operation of said spacing or penultimate mechanism said movable rack may be retracted automatically the distance of one tooth and so on through the advance movement of said platen but said gearing acting upon the return movement of the platen to automatically move the movable rack in the reverse direction one tooth for every tooth which it retracted said rack in the advance movement of the platen, thereby acting to shorten the connection between said platen and driving mechanism in the advance movement said to correspondingly lengthen it in the return movement, substantially as and for the purpose set forth.

5. The combination of a number-register, shifting driving mechanism for actuating the different members of said register, a series of numeral-keys for positioning and actuating said register-driving mechanism, a type for each of said numeral-keys bearing the character corresponding thereto and actuated by its respective key to print, a shifting platen moved step by step in its advance movement by the operation of each of said keys and against which the type set, spacing or penultimate mechanism for spacing or penultimate in certain numeral order the figures constituting a printed number and acting to shift the platen at each operation, connections between said platen and register-driving mechanism and means for shortening said connection a distance equal to one step of advance movement of the platen each time said spacing or penultimate mechanism is actuated and for lengthening said connection correspondingly upon the return movement of the platen, each means comprising the following parts, namely, a stationary toothed rack having at least the same number of teeth as the number of character-spaces to the line, a support moving in fixed relation with the shifting platen and provided with a movable toothed rack adapted to move in either direction of its length in the direction in which the platen travels, a gear-wheel mounted upon said support and in mesh with the teeth of said stationary rack and trip-disk moving in fixed relation to the said gear-wheel and adapted to lock with the toothed wheel and thereby hold the movable rack fixed while the gear of the stationary rack moves over

said mechanism for shifting the platen one step at each operation, and means for shortening the connection between said platen and register-driving mechanism a distance equal to one step of advance movement of said platen each time said spacing or penultimate mechanism is actuated, substantially as and for the purpose set forth.

6. The combination of a number-register, shifting driving mechanism for actuating the different members of said register, a series of numeral-keys for positioning and actuating said register-driving mechanism, a type for each of said numeral-keys bearing the character corresponding thereto and actuated by its respective key, a shifting platen against which the type set and means for shifting the platen one step upon the operation of each of said numeral-keys, connections between the shifting platen and the shifting register-driving mechanism whereby the latter is advanced a step each time the platen is shifted a step by the numeral-key, spacing or penultimate mechanism for shifting the platen one step at each operation, and means for shortening the connection between said platen and register-driving mechanism a distance equal to one step of advance movement of said platen each time said spacing or penultimate mechanism is actuated and for lengthening said connection a distance of one step on the return movement of the platen for each step that such connection is shortened in the advance movement of the platen, substantially as and for the purpose set forth.

7. The combination of a number-register, shifting driving mechanism for actuating the different members of said register, a series of numeral-keys for positioning and actuating said register-driving mechanism, a type for each of said numeral-keys having thereon the character corresponding to the key and actuated by its respective key to print, a shifting platen moved step by step in its advance movement by the operation of each of said keys and against which the type set, spacing or penultimate mechanism for spacing or penultimate in certain numeral order the figures constituting a printed number and acting to shift the platen at each operation, connections between said platen and register-driving mechanism and means for shortening said connection a distance equal to one step of advance movement of the platen each time said spacing or penultimate mechanism is actuated and for lengthening said connection correspondingly upon the return movement of the platen, each means comprising the following parts, namely, a stationary toothed rack having at least the same number of teeth as the number of character-spaces to the line, a support moving in fixed relation with the shifting platen and provided with a movable toothed rack adapted to move in either direction of its length in the direction in which the platen travels, a suitable connection between said movable rack and the said register-driving mechanism, gearing arranged between the teeth of the two said racks in such relation that upon an advance movement of the platen said movable rack may be advanced likewise in fixed relation therewith a predetermined number of teeth, say three teeth, and then upon the operation of said spacing or penultimate mechanism said movable rack may be retracted automatically the distance of one tooth and so on through the advance movement of said platen but said gearing acting upon the return movement of the platen to automatically move the movable rack in the reverse direction one tooth for every tooth which it retracted said rack in the advance movement of the platen, thereby acting to shorten the connection between said platen and driving mechanism in the advance movement said to correspondingly lengthen it in the return movement, substantially as and for the purpose set forth.

8. The combination of a number-register, shifting driving mechanism for actuating the different members of said register, a series of numeral-keys for positioning and actuating said register-driving mechanism, a type for each of said numeral-keys having thereon the character corresponding to the key and actuated by its respective key to print, a shifting platen moved step by step in its advance movement by the operation of each of said keys and against which the type set, spacing or penultimate mechanism for spacing or penultimate in certain numeral order the figures constituting a printed number and acting to shift the platen at each operation, connections between said platen and register-driving mechanism and means for shortening said connection a distance equal to one step of advance movement of the platen each time said spacing or penultimate mechanism is actuated and for lengthening said connection correspondingly upon the return movement of the platen, each means comprising the following parts, namely, a stationary toothed rack having at least the same number of teeth as the number of character-spaces to the line, a support moving in fixed relation with the shifting platen and provided with a movable toothed rack adapted to move in either direction of its length in the direction in which the platen travels, a gear-wheel mounted upon said support and in mesh with the teeth of said stationary rack and trip-disk moving in fixed relation to the said gear-wheel and adapted to lock with the toothed wheel and thereby hold the movable rack fixed while the gear of the stationary rack moves over

a predetermined number of teeth thereof, say three teeth, and then to trip and actuate said toothed wheel and thereby move said movable rack in the reverse direction in which its support moves, substantially as and for the purpose set forth.

698,615. RAIL-JUMP. EDWARD KANONIKY, West Lohrweg, Pa. Filed Jan. 6, 1902. Serial No. 65,982. (No model.)

Claim.—1. In a metallic tie and rail-fitter, an I-beam metallic tie receiving the rails on the head thereof, fish-plates secured on their lower flanges and for receiving the rail-bases secured upon the head of the tie and engaging the web thereof, and vertically-extending wedges received in openings provided therefor in the head of the tie and on each side of the web of the tie, the wedges engaging the web of the tie and the outer face of the fish-plates, substantially as described.

2. In a metallic tie and rail-fitter, an I-beam metallic tie receiving the rails on the head thereof, fish-plates secured on the head of the tie and engaging the web, said fish-plates being secured on their inner flanges for receiving the rail-bases, said fish-plates extending beyond the sides of the tie and engaging the upper and lower flanges of the rail-bases, at that point, a series of studs carried by one of the fish-plates and extending into the other fish-plate, and vertically-extending wedges engaging through the head of the tie and abutting against the outer face of the fish-plates, substantially as described.

698,616. LIFTING AND CARRYING DEVICE. JOHN H. BURNHAM, Marysville, Ohio. Filed Aug. 2, 1901. Serial No. 71,804. (No model.)

Claim.—1. In a lifting and carrying device, the combination of opposing side frames, comprising pairs of standards 1, connected here 2 jointly connecting said standards as described, a transverse handle-bar 7, spring-wires connecting the latter with the upper ends of said standards and clamping-wires connecting the lower ends of the standards of opposite pairs, substantially as specified.

698,617. DRIER. FREDERICK S. ALLEN, Boston, Mass. Filed Feb. 2, 1901. Serial No. 65,983. (No model.)

Claim.—1. In a drier, a drying-bin, a series of disconnected trays, tray-propelling means within the bin, devices independent of said tray-propelling means and placed therefor for automatically advancing the trays into the bin and withdrawing them therefrom, means to automatically fill the trays approaching the bin, means to automatically discharge the trays leaving the bin, and devices for automatically conducting the trays from the withdrawing and discharging devices to the filling means and advancing device.

2. In a drier, a drying-bin, a series of trays, a device for filling the

trays, and means for conducting the trays at a relatively slow speed while being filled by said device, and at a relatively fast speed from said device into the drying-bin.

3. In a drier, a drying-bin, a series of trays, a device for filling the trays, a carrier for advancing the trays beneath said filling device to be filled, and from said device into the drying-bin, and means for propelling said carrier at a relatively slow speed while the tray is being filled, and at a relatively fast speed while it is being advanced into the drying-bin.

4. In a drier, a drying-bin, a series of trays, a device for filling the trays, a carrier for advancing the trays beneath said filling device to be filled, and from said device into the drying-bin, two driving mechanisms operated at different speeds, clutches for connecting said mechanisms to and disconnecting them from the carrier, and means for alternately operating said clutches.

5. In a drier, a series of trays, a carrier adapted to advance said trays, slow and fast motion carrier-propelling mechanisms, a carrier-propelling shaft, a pawl-and-ratchet clutch adapted to connect the slow-motion mechanism with the shaft, a crown toothed clutch adapted to connect the fast-motion mechanism with the shaft, and means to connect and disconnect the last said clutch.

6. In a drier, a series of trays, a carrier adapted to advance said trays, carrier-propelling mechanism, a clutch adapted to connect said mechanism to and disconnect it from the carrier, a spring adapted to throw the clutch, means to put said spring ineffectively under clutch-throwing stress prior to the throwing of the clutch, and means controlled by the position of the carrier for rendering said spring operative.

7. In a drier, a series of trays, and a tray-filling device comprising a hopper, an inclined distributing-pan below the hopper, means to vibrate the hopper and pan horizontally, and means to vibrate the pan vertically.

8. In a drier, a series of trays, and a tray-filling device comprising a hopper, an inclined distributing-pan below the hopper, means to vibrate the hopper and pan horizontally, means to vibrate the pan vertically, and means for adjusting the lower limit of inclination of the pan to vary the feed.

9. In a drier, a series of trays, a tray-filling device adapted to feed loose or broken material by vibratory agitation of the device, means to intermittently rotate the device, and means to intermittently advance the trays beneath said device during periods coinciding with the periods of agitation of said device.

10. In a drier, a series of disconnected trays, a dumping-frame having provision for receiving a tray from either end, means to automatically propel the trays in one direction into and out of said frame, and automatic mechanism timed with the propelling means to intermittently rotate said frame a half-rotation at a time in one direction.

11. In a drier, a drying-bin, a series of trays, a dumping-frame, a tray-carrying guide beyond said frame, and a carrier adapted to directly propel the trays from the drying-bin into the dumping-frame, and from

and dumping-frame into the guide through the medium of the tray thus propelled.

12. In a drier, a drying-bin, a series of trays, an invertible dumping-frame, intermittently-acting means to lower said frame, an automatic latch independent of said means for locking said frame, and intermittently-acting means for releasing said latch.

13. In a drier, a drying-bin, a series of trays, an invertible dumping-frame, automatically-projected tray-retaining means on said frame, and means actuated by the movement of said frame into tray-receiving position, for retracting said tray-retaining means.

14. In a drier, a drying-bin, a series of trays, a dumping-frame, a tray-receiving guide beyond said frame, and from thence into the guide through the medium of a tray thus propelled, and means to give the tray in the guide a limited additional movement to clear it from the tray in the frame.

15. In a drier, a series of trays, tray-dumping means located at an elevated level, tray-discharging means located at a lower level, means to advance the trays at the two levels, and independent means to elevate the empty trays from the discharging-level to the filling-level.

16. In a drier, a series of trays, a substantially vertical carrier for handling empty trays, means to conduct the trays horizontally toward said carrier, and a swinging tray-frame movable into a substantially horizontal position to receive the trays and into a substantially vertical position to deliver them to the carrier.

17. In a drier, a series of trays, a substantially vertical carrier for handling empty trays, means to conduct the trays horizontally away from said carrier, and a swinging tray-frame movable into a substantially vertical position to receive the trays from the carrier, and into a substantially horizontal position to deliver them to said discharging means.

18. In a drier, a series of trays, a substantially vertical carrier for handling empty trays, and swinging frames at the upper and lower ends of said carrier for delivering the trays to and receiving them from the carrier and changing their posture.

19. In a drier, a series of trays, a substantially vertical carrier for handling empty trays, swinging frames at the upper and lower ends of said carrier for delivering the trays to and receiving them from the carrier and changing their posture, and a connection between said frames whereby they are swung in unison.

20. In a drier, a series of trays, a substantially vertical carrier for handling empty trays, a swinging tray-frame co-operating with said carrier, and movable from a tray-receiving position to a tray-delivering position, automatically-projected tray-retaining means on said frame, and means actuated by the movement of the frame into tray-receiving position, for retracting said tray-retaining means.

21. In a drier, a series of trays having perforated bottoms, means to invert said trays for the purpose of discharging their contents, and a brush arranged to act through the bottoms of the discharged trays to clear them of clinging material.

22. In a drier, means to support a series of trays in a vertical stack, means to cause an uniform downward progression of the stack, and a drying-bin having a stack-compartment including the stack, dry-air inlets to said compartment located at different levels, moist-air outlets therefrom located at different levels and alternating with the inlets, and means to supply heated air simultaneously to the different inlets.

23. In a drier, a drying-bin, means to support and propel a series of trays in the form of a vertical stack in said bin, a middle stack compartment and two side compartments in said bin, passages connecting said middle and side compartments at different vertical locations, means to heat the lower part of the middle compartment, means to exhaust the upper part of said compartment, and a distributing-chamber connecting with the lower and intermediate parts of said middle compartment.

698,618. GRAB-MOLDING APPARATUS. JOHN AMMON, Hopkinton, Mass., assignor to Oliver Company, Boston, Mass., a Corporation of Maine. Filed Oct. 26, 1901. Serial No. 96,417. (No model.)

Claim.—1. In grab-molding apparatus, a fixed stripper-plate having a pattern-opening, a pattern-carrier movable toward and from the stripper-plate, means to effect such movement of the pattern-carrier, a pattern rotatably mounted on the pattern-carrier, and including a spiral gear portion, a lateral finger rigidly connected with the pattern, a fixed director having a pitch-face corresponding to the pitch of the gear, and means to yieldingly press the finger against the pitch-face, movement of the pattern to draw it from the mold casting, by co-operation of the finger and the director, to properly rotate said pattern.

2. In grab-molding apparatus, a fixed stripper-plate having a pattern-opening, a pattern-carrier movable toward and from the stripper-plate and having an upright tubular bearing, means to effect such movement of the pattern-carrier, a pattern having a tubular chuck rotatably mounted in said bearing, a lateral finger secured to the chuck below the

bearing, a fixed director having a pitch-face over which the finger travels, to impart relative movement to the pattern when moved longitudinally, and a spring to yieldingly press the finger against the pitch-face.

3. In grab-molding apparatus, a fixed stripper-plate having a plurality of pattern-openings, a plurality of co-operating and rotatably-mounted patterns bodily movable toward and from the stripper-plate and each having a spiral gear portion, means to effect such bodily movement of the patterns, a common fixed director symmetrically located relatively to the several patterns and having a like number of pitch-faces corresponding to the pitch of the gear portions, and laterally-extended flanges rigidly connected with the several patterns and at their inner ends engaging the several pitch-faces of the said director, whereby movement of the patterns longitudinally will, through the flanges and pitch-faces, rotate the patterns in correspondence with the pitch of the gear portions, to draw the same from the mold.

4. In grab-molding apparatus, a stripper-plate, a co-operating hollow pattern having a side opening, a pattern-plate in which the pattern is rotatably mounted, means to move the pattern-plate toward and from the stripper-plate, a lag-print carrier pivotally mounted within the pattern and having a lag-print thereon to extend through the side opening, the lower end of the carrier being offset from the axis of rotation of the pattern, means co-operating with said offset end to move the carrier to retract the lag-print and to control the offset and relatively to the axis of rotation of the pattern, and means to rotate the pattern, when it is moved longitudinally and bodily by movement of the pattern-plate.

5. In grab-molding apparatus, a stripper-plate, a co-operating hollow pattern, having a side opening, a pattern-plate in which the pattern is rotatably mounted, means to move the pattern-plate toward and from the stripper-plate, a lag-print carrier pivotally mounted within the pattern, and having a lag-print thereon to extend through the side opening, the lower end of the carrier being offset from the axis of rotation of the pattern, means co-operating with the offset end and supported by the pattern-plate to control the lower end of the carrier with the axis of the pattern, and means to rotate the pattern when it is moved longitudinally.

6. In grab-molding apparatus, a fixed stripper-plate, a pattern-plate movable toward and from said plate, means to effect such movement of the pattern-plate, a pattern rotatably mounted on said pattern-plate and having a spiral gear portion and a hollow hub portion provided with a side opening, a lag-print carrier pivotally mounted within the hub portion and laterally offset at its lower end from the axis of rotation of said hub portion, a sliding, manually-operated actuator co-operating with the offset end of the carrier and supported by the pattern-plate, a lag-print on the carrier and adapted to extend laterally through the side opening in the hub portion of the pattern, means to automatically rotate the pattern when moved longitudinally, to thereby draw the spiral gear portion thereof, and means to prevent relative movement of the pattern until the sliding actuator has been moved to retract the lag-print and to also control the offset end of the carrier.

698,619. PACKAGE FASTENER AND SEAL. WALTER S. ARMSTRONG, Bathurst, N.Y. Filed Aug. 12, 1901. Serial No. 71,530. (No model.)

Claim.—1. In a device of the class specified, the combination with a heap, of a staple provided with a locking member to project through the heap and having means disposed within the heap-opening for exerting downward draft upon the heap.

2. In a device of the character specified, a heap having a staple-opening provided at its lower extremity with a laterally-projecting cam-rocker, in combination with a pivoted staple having a locking member to pass through the opening and bear against the heap and a cam to engage the cam-rocker.

3. In a device of the character specified, a heap having its staple-opening provided with a cam-rocker, in combination with a pivoted staple having a cam to engage the rocker, and means for locking the staple against turning.

4. The combination with a receptacle carrying a pivoted cam-bearing staple adapted for movement in a plane parallel to that portion of the receptacle with which it is associated, of a cleavage carrying a heap adapted for movement at right angles to the staple, said heap being provided with a slot to straddle the staple and having a cam-rocker therein to engage the cam portion thereof.

5. The combination with a receptacle, of a plate carrying an off-center and a pivoted cam-bearing staple provided with an off-center to align with that of the keeper, and a cover carrying a heap provided with a slot to straddle the staple and having a cam-rocker to engage the cam portion thereof, and fastening means to engage the off-center in the keeper and the staple.

6. The combination with a receptacle of a plate secured to the receptacle and carrying a pivoted cam-bearing staple provided with an off-center, and an off-center keeper, a heap carried by the receptacle-cover and having a slot to straddle the staple and a cam-rocker to engage the cam portion thereof, and a cam-carrying wire to engage the off-center in the keeper and in the staple.

698,620. SHAPE-ROLLER AND BRACKET THEREFOR. CHAS. A. BAKER, Washington, Wm., assignor, by mesne assignments, to Stewart-Hartshorn Company, a Corporation of New Jersey. Filed Feb. 26, 1901. Serial No. 44,000. (No model.)

Claim.—1. In spring shade-roller, the combination with a roller having a cavity in one end, of a plate fixed to said end having a central opening, a spring-carrying spindle within said cavity having a roller-supporting spur extending freely through said opening, bearing-balls interposed between said end plate and said spur and means for holding said balls in position about said central opening.

2. In spring shade-roller, the combination with a roller having a cavity in one end, of a plate fixed to said end having a central opening, a spring-carrying spindle within said cavity having a roller-supporting spur extending freely through said opening, bearing-balls interposed between said end plate and said spur, said plate and spur being provided with grooved recesses for said bearing-balls, and means for holding the same in position about the central opening.

3. In spring shade-roller, the combination with a roller having a cavity in one end, of a plate fixed to said end having a central opening, a spring-carrying spindle within said cavity having a supporting-spur extending through said opening, bearing-balls interposed between said plate and said spur, said plate and spur being provided with grooved recesses for said bearing-balls and means for holding the same in position about the central opening.

4. In spring shade-roller, the combination with a roller having a cavity in one end, of a plate fixed to said end having a central opening, a spindle within said cavity carrying a spring secured at its inner end to said spindle and at its outer end to the roller, said spindle having a roller-supporting spur extending through said central opening and balls interposed between the end of said spindle and said plate and bearing upon said spur, and means for holding said balls in position about said central opening.

5. In spring shade-roller, the combination with a roller having a cavity in one end, of a plate fixed to said end having a central opening,

a spring-supporting spindle within said cavity having a roller-supporting spur extending freely through said opening, bearing-balls interposed between said plate and the end of said spindle, and means for holding said balls in position about said central opening.

6. In spring shade-roller, the combination with a roller having a cavity in one end, of a plate fixed to said end having a central opening, a spring-supporting spindle within said cavity having a roller-supporting spur extending freely through said central opening, a flange on the outer end of said spindle having a cup-shaped end flange, and bearing-balls within said cup-shaped flange and held in position thereby against said end plate and about the central opening therein.

7. In spring shade-roller, the combination with a roller having a cavity in one end, of a plate fixed to said end provided with a central opening and having a grooved recess about said opening, a spindle within said cavity carrying a spring secured at its inner end to said spindle, and at its outer end to the roller, said spindle having a roller-supporting spur extending freely through the opening in said plate, a flange on the outer end of said spindle provided with a cup-shaped end flange and bearing-balls within said cup-shaped flange and held in position thereby in engagement with the grooved recess in said end plate.

8. In a fixture for shade-roller, the combination with a roller having a shoulder and fixed to one end thereof, of a bracket for said end adapted to be rigidly held in position and provided with an opening for receiving said end, said bracket being formed of two separate sheet-metal sections having inwardly-extending annular flanges forming the periphery of said opening, an annular depression in the body of one of said sections forming a ball-chamber intermediate said flanges, and bearing-balls in said chamber, said sections being rigidly secured together whereby said bearing-balls will be permanently retained in position between said flanges and about the periphery of said opening.

9. A bracket for shade-roller provided with an opening for receiving the end and end of a roller said bracket being formed of two separate sections having inwardly-extending annular flanges forming the periphery of said opening, bearing-balls retained in position between said flanges about the periphery of said opening and held upon one of said sections for engaging the other section, whereby said parts are secured together.

10. In a spring shade-roller having an end cap-piece, an end plate 17 stamped up from sheet metal and having the outwardly-extending peripheral lugs 20 for engaging the end cap-piece of the roller, the inwardly-extending peripheral lugs 21 for engaging the end of the roller, a central opening and the V-shaped strap-lugs 22, substantially as described.

11. In a shade-roller having an operating-spring, an end plate 17 therefor, stamped up from sheet metal and having the inwardly-extending peripheral lugs 21 for engaging the end of the roller, a central opening and the V-shaped, spring-supporting strap-lugs 22, substantially as described.

698,621. INDEX-FILER. WILLIAM H. BALL, Danversville, Ohio. Filed Dec. 21, 1900. Serial No. 41,716. (No model.)

Claim.—1. An index-filer, consisting in combination with the angled rack of the tube, the wire journaled to the rack and having a notch, one end of said wire bent at right angles, a spring secured at one end to the wall of the rack, its free end normally resting in the notch in the wire to hold same with one of its ends in said tube, and also serving as a stop to hold the wire to the rack, as set forth.

2. In combination with the angled rack, the tube, the index-retaining wire bent as above and journaled to the wall of the rack, a spring secured to the outer wall of the rack and its free end bearing yieldingly against said wire, and the inner wall of the rack being recessed to receive one end of the wire as the latter is swung out of the path of the index leaves and sheets as they are placed upon or removed from the file, as set forth.

698,622. BEVEL-LOC. JOHN C. BARKER, Whitebury, N.Y. Filed Sept. 2, 1901. Serial No. 74,097. (No model.)

Claim.—In an envelope, the combination with the body portion, of side flaps having slots formed therein, an upper flap carrying a gummed

tongue, a lower flap having cut-away sides with a slot formed therein, all of said slots registering when the flaps are in their normal position, a second lower flap, said side flaps being first placed in position, the lower flap being then bent to engage the outer face of said side flaps, and said second lower flap being inserted between the inner faces of the side flaps and the body portion of the overlap, and lastly said gummed tongue being inserted through all of said registering slots and engaging the inner faces of the flaps, substantially as described.

698,628. STOVEPIPE. GEORGE S. RABBITT, JR. Filed Jan. 23, 1901. Serial No. 44,988. (No model.)

Claim.—1. As a new article of manufacture, a knock-down pipe-section made of two conical halves, both halves being provided near one edge with the overlapping tongues *d* and one half being provided with the turned-back tongue *f* passing through one of the apertures in the other half formed by clamping out the tongue *d*, all combined and cooperating substantially as and for the purpose described.

2. As a new article of manufacture, a knock-down pipe-section made of two conical halves, means for rigidly securing said halves at one pair of edges, the flattened-S-shaped strip *g* secured to the other edge of one half, and into which the corresponding edge of the other half projects as it can be moved therein; substantially as described.

3. As a new article of manufacture, a knock-down pipe-section made of two conical halves, means for rigidly securing said halves at one pair of edges, the flattened-S-shaped strip *g* secured to the other edge of one half by the turned-back tongue *j* on said edge passing through the aperture *h* in said strip, and into which the corresponding edge of the other half projects so that it can be moved therein; substantially as described.

4. As a new article of manufacture, a knock-down pipe-section made of two conical halves, means for rigidly securing said halves at one pair of edges, the flattened strip *g* secured to the other edge of one half by the turned-back tongue *j* on said edge passing through the aperture *h* in said strip which is provided with the groove *m* into which the corresponding edge of the other half projects so that it can be moved therein, and connections at one end consisting of the turned-back tongue *n* passing through the notch *c*; substantially as and for the purpose described.

698,624. PLOW-ENDER ATTACHMENT FOR CULTIVATOR-PLOW. JOHN W. BATES, Batesville, Mo. Filed Feb. 10, 1902. Serial No. 94,880. (No model.)

Claim.—1. In a plow-ender of the class described, a fender-wing, a reversible fender-disk in rear thereof and extending below the same and means to carry said wing and disk, substantially as described.

2. In a plow-ender of the class described, the combination of a bar, a fender carried thereby, means to connect the bar to a plow-beam, a guide-bar having means whereby it may be attached to a plow-handle, a longitudinally-adjustable bar carried by said guide-bar and connections between said adjustable bar and the bar which carries the fender, whereby the latter may be adjusted, substantially as described.

3. In a plow-ender of the class described, the combination of a link and means to attach the same to a plow-beam, a bar carrying a fender element having its front end pivotally connected to the link, a guide-bar having means whereby its rear end may be attached to a plow-handle, a

clip to engage said handle, means to adjustably secure the front end of the guide-bar to said clip, a longitudinally-movable adjusting-bar carried by said guide-bar and a connection between said adjusting-bar and the rear end of the fender-carrying bar, substantially as described.

4. In combination with a fender adapted to be raised and lowered, a guide, a longitudinally-movable adjusting-bar carried by the guide and connected to the fender, a fixed stop, coating adjusting elements with which the adjusting-bar is provided to engage said stop and a spring bearing on said adjusting-bar to normally lock the latter to the stop, substantially as described.

698,625. LIQUID-METER. SEYMOUR BROWNE, Brest-le-Duc, France. Filed Jan. 14, 1902. Serial No. 92,789. (No model.)

Claim.—1. In a liquid-meter of the turbine class, a turbine, a regulator revolving with the turbine and operating a valve which opens the discharge-orifice in proportion to the quantity delivered and which at rest completely closes this orifice, the putting in motion of the turbine on the opening of the cock being permitted by the compression of air in the turbine-chamber.

2. In a liquid-meter of the turbine class, the combination with a cock of any suitable character of a closed chamber containing the turbine, a centrifugal regulator mounted on and rotating with the turbine-shaft, a valve operated by connection from the regulator, a play or lost motion existing between the compression from the regulator and the valve, an opening forming a seat for the valve and communicating with the delivery-spout, means for regulating the height of the turbine-shaft, a passage delivering the liquid from the outlet of the cock to the turbine tangentially to the latter, and a screw-down rod controlling the cock-outlet, substantially as herein set forth.

698,626. FOLDING FOOTBOARD FOR IRON BEDSTEAD. LAWRENCE E. BROWN, Minneapolis, Minn. Filed May 15, 1901. Serial No. 93,948. (No model.)

Claim.—1. A detachable footboard for iron bedsteads, comprising

the board-sections *a* and *b*, the hinges *c* connecting the said board-sections, and right brackets secured to said board-section *a* and adapting the same to be rigidly but detachably secured with respect to the bedstead and other parts of the bed, and which board-section *b* is adapted to be folded flat over the foot end of a mattress, substantially as and for the purposes set forth.

2. The combination with a bedstead having a foot-board, of a foot-board comprising board-sections *a* and *b*, hinges connecting said board-sections, and brackets supporting said board-section *a* with respect to the bedstead in a position forward of the foot-board of the said bed, whereby said section *b* may be folded flat on top of the mattress and the bed-clothes may be placed over said board-section and between said relatively fixed board-section *a* and the foot-board of the bed.

698,627. MACHINE FOR CLEANING BRICKS. LAWRENCE E. BROWN, Minneapolis, Minn. Filed June 12, 1901. Serial No. 94,311. (No model.)

Claim.—1. In a machine for cleaning mortar from bricks, the combination of the bed of the machine having curved therein suitable tracks, the frame resting on said tracks and capable of free movements thereon, the combined outer and scraper bars which cross each other and are supported within and carried by said frame, the gage secured to the top of said bed immediately above said frame, and means for imparting reciprocating movements to said frame, substantially as set forth.

2. In a machine for cleaning mortar from bricks, the combination of the bed having suitable tracks curved therein, the frame resting upon said tracks and capable of free movements thereon, the combined outer and scraper bars which cross each other and are supported within and carried by said frame, the central gage-plate secured on top of said bed and having corresponding legs in its opposite edges, the auxiliary adjustable gage-plates bolted on top of said bed on opposite sides of the central gage and separated from the latter by predetermined spaces, and means for imparting reciprocating movements to said frame, substantially as set forth.

3. In a machine for cleaning mortar from bricks, the combination of the bed of the machine having curved therein on its inside suitable tracks and having journaled at one end a shaft, the power-pulley and crank-wheel carried by said shaft, the frame resting upon said tracks and capable of free movements thereon, the combined outer and scraper bars which cross each other and are supported within and carried by said frame, the plates whose ends are respectively pivoted to said frame and to a crank-plate carried by said wheel, the central gage bolted to the top of said bed and having corresponding legs in its opposite edges, and the adjustable auxiliary gage-plates also bolted to the top of said bed and normally separated from the central gage-plate by predetermined spaces, substantially as and for the purposes set forth.

698,628. CAMERA. EDGAR E. DILLARD, Springfield, Mass. Filed July 15, 1901. Serial No. 94,416. (No model.)

Claim.—1. In a camera, the combination with the camera-casing adapted for attachment to a suitable stand, of a bed for the camera-front pivotally supported from the casing, and a movable member within said casing to which the bed is hinged, whereby said member is extended or retracted the bed will receive a corresponding movement and at the same time change its inclination substantially as and for the purpose set forth.

2. In a camera, the combination with the camera-casing adapted for attachment to a suitable stand, of a swinging bed for the camera-front, and a swinging support within said casing, having a hinge connection with the rear of said bed, substantially as and for the purpose set forth.

3. In a camera, the combination with a camera-casing adapted for attachment to a suitable stand, of a bed for the camera-front, swinging supports to which said bed is pivotally connected, and a swinging support within the casing, having a hinge connection with the said bed, substantially as and for the purpose set forth.

4. In a camera, the combination with the camera-casing adapted for attachment to a suitable stand, of a swinging bed for the camera-front, having a pivotal connection with its swinging supports, a movable supporting member within the casing, to which the bed is hinged, and means for extending and retracting said movable member to swing and tilt the bed, substantially as and for the purpose set forth.

5. In a camera, the combination with the camera-casing adapted for attachment to a suitable stand, of a swinging bed for the camera-front, having a pivotal connection with its swinging supports, a movable supporting member within the casing, to which the bed is hinged, means for extending and retracting said member to swing and tilt the bed, and means for locking said member at any point of its movement, substantially as and for the purpose set forth.

6. In a camera, the combination with the camera-casing adapted for attachment to a suitable stand, of a swinging bed for the camera-front, having a pivotal connection with its swinging supports, a movable supporting member within the casing, to which the bed is hinged, the same carrying one or more rods, and a rotatable shaft having one or more plates for engaging said rods or racks, whereby to extend or retract said member to swing and tilt the bed, substantially as and for the purpose set forth.

7. In a camera, the combination with a camera-casing adapted for attachment to a suitable stand, of a swinging bed for the camera-front, having a pivotal connection with its swinging supports, a movable supporting member within the casing, to which the bed is hinged, the same carrying one or more rods, a rotatable shaft mounted to slide longitudinally, and having one or more plates for engagement with said rods or racks whereby to extend or retract said member to swing and tilt the bed, and a locking-plate secured to the casing having an edge arranged to enter between the teeth of one of said plates when the shaft is slid in one direction, substantially as and for the purpose set forth.

8. In a camera, the combination with a camera-casing, adapted for attachment to a suitable stand, of a swinging bed for the camera-front, having a pivotal connection with its swinging supports, a movable supporting member within the casing, to which the bed is hinged, the same carrying

prong a cross-piece in proximity to the bottom of the casing and carried by swinging supports, and having a convex under surface on which is provided one or more racks, and a rotatable shaft having one or more pinions for engagement with said rack or racks, whereby to extend or retract the said member to swing and tilt the bed, substantially as and for the purpose set forth.

3. In a camera, the combination with a camera-casing, adapted for attachment to a suitable stand, a falling front having a link connection with the casing, a movable member within said casing to which said front is hinged, and an extension carried by said front and adapted to close the space intermediate the hinge connection and the bottom of the casing, when covering the front opening thereof, substantially as set forth.

698,699. REVERSE-ENGINEERING MECHANISM. LEO J. DUNN, Sturges, Mich. Filed Feb. 28, 1901. Serial No. 44,731. (No model.)

Claim.—1. In a register mechanism for coins the combination of a suitable casing containing a slot for the introduction of coins; a register within said casing, supported on a suitable shaft supported in a suitable framework, having its lower member-wheel provided with teeth; a cam-plate; a shaft through said plate; a body with a sleeve-like extension supported suitably on said shaft and connected to rotate therewith, containing a longitudinal slot to receive coins; and the said sleeve part containing guiding-grooves; fingers secured to the said framework and adapted to engage said grooves and hold the sleeve in a given position through a predetermined part of its rotation; a spring to return said sleeve to the normal position; and dogs carried by said sleeve to engage the number-wheels when they are moved into engagement by the introduction of a coin and rotated by suitable means, as specified.

2. In a register mechanism for coins the combination of a register, supported on a suitable shaft supported in a suitable framework, having its lower member-wheel provided with teeth; a cam-plate; a shaft through said plate; a body with a sleeve-like extension supported suitably on said shaft and connected to rotate therewith, containing a longitudinal slot to receive coins; and the said sleeve part containing guiding-grooves; fingers secured to the said framework and adapted to engage said grooves and hold the sleeve in a given position through a predetermined part of its rotation; a spring to return said sleeve to the normal position; and dogs carried by said sleeve to engage the number-wheels when they are moved into engagement by the introduction of a coin and rotated by suitable means, as specified.

3. In a register mechanism the combination of a suitable register; a cam-plate; a movable part adjacent to said cam-plate containing a recess to receive a coin; engaging means actuated by said movable part to rotate the register when a coin is introduced; a guiding means to engage said movable part when it is actuated by a coin and hold it in engagement with the register, a predetermined portion of its movement to register the value of the coin, ceasing as specified.

4. In a register mechanism the combination of a suitable register a cam-plate; a movable part adjacent to said cam-plate containing a recess to receive a coin; engaging means actuated by said movable part to rotate the register when a coin is introduced; and means to hold it in engagement with the register, a predetermined portion of its movement to register the value of the coin, ceasing as specified.

5. In a register mechanism the combination of a register; a relatively fixed part and movable part; a recess between the two for the reception of a coin; actuating means on the movable part for the register; guides for the movable part to hold it in actuating connection with the register for periods predetermined by the size of the coin to be registered to register the value of the coin.

6. In a register mechanism the combination of a register; a relatively fixed part and movable part; a recess between the two for the reception of a coin; actuating means on the movable part for actuating the register for periods predetermined by the size of the coin to be registered to register the value of the coin.

7. In a register mechanism the combination of a register; a central shaft therethrough; a sliding sleeve thereon containing the guiding-grooves *d*, and other *f* with slot *f'* therein; finger *I* and *I'* to engage said grooves; means of actuating said shaft to move it lengthwise and rotate it whereby different degrees of movement of the register are caused, ceasing as specified.

8. In a register mechanism the combination of a register; a central shaft therethrough; a sliding sleeve thereon containing the guiding-grooves *d* and other *f* with slot *f'* therein; finger *I* with projection *I'* thereon to engage said grooves; means of actuating said shaft to move it lengthwise and rotate it whereby the different movements are caused, ceasing as specified.

9. In a register mechanism the combination of a register; an engaging part therefor; a cam-plate *H* having cam *n* and recess *n'*; a movable part *D* opposite containing slot *D'* to receive cam *n* and carry them against the cam-plate whereby the part is actuated a varying predetermined amount to register the coin.

698,680. GRATE. EDWIN E. CAMBER, Newark, N. J. Filed Mar. 4, 1901. Serial No. 44,821. (No model.)

Claim.—1. A stove comprising a casing having an opening in one of its walls, a fire-pot adjacent said opening, and a grate extending from the top to the bottom of and pivotally supported horizontally in said opening in the casing, adapted to be reversed to increase the size of the fire-pot in one position and decrease said fire-pot when turned over in the opposite position, substantially as described.

2. A stove comprising a casing having an opening in one of its walls, a fire-pot, a pivoted and a hooked shaped grate in said opening adapted to increase the capacity of the fire-pot when turned in one position and decrease the capacity of said fire-pot when reversed in a second position, substantially as described.

3. A stove comprising a casing having an opening in one of its walls, a fire-pot, and means pivoted and located in said opening whereby the capacity of the fire-pot may be increased when said means are moved in one position and decreased when said means are turned over on its pivot to present the opposite face to the fire-pot in a second position, substantially as described.

4. A stove comprising a casing having an opening in one of its walls, a fire-pot, a grate in the bottom of said fire-pot, a hooked shape pivoted grate in said opening, said grate being adapted to be turned over and in either position form a continuation of the grate in the bottom of the fire-pot to increase or decrease said fire-pot, substantially as described.

5. A stove comprising a casing having an opening in one of its walls, a fire-pot, a pivoted hooked shape grate in said opening, a frame surrounding said grate, a door fitting said frame, and a bracket adapted to be supported in the space between the grate and the door, substantially as described.

6. A stove comprising a casing having an opening in one of its walls, a fire-pot, a swinging grate located in said opening, a frame surrounding the grate, a door fitting said frame, a bracket adapted to be supported in the space between the grate and the door, and a drip-pen located below said bracket and the line of the fire-pot, substantially as described.

7. A stove comprising a casing having an opening in one of its walls, a fire-pot, a swinging grate located in said opening, a frame surrounding the grate, a door fitting said frame, a loose pivot connection between the door and the frame adapted to permit of the door being brought in alignment with its seat, but spaced therefrom, substantially as described.

8. A stove comprising a casing having an opening in one of its walls, a swinging grate located in said opening means for supporting a bracket

in close proximity to said grate, and a pocket formed at the bottom of said swinging grate to receive a drip-pen, substantially as described.

9. A stove comprising a casing having an opening in one of its walls, a grate located in said opening, a door adapted to cover said opening, means-covered trunks or tubes attached to said door, and a dotted plate slidable on the grate and in front of said door windows, substantially as described.

10. A stove comprising a casing having an opening in one of its walls, a frame having flanged ends in said opening, a hooked shape grate pivoted and supported in said frame adapted to be swung to increase or decrease the capacity of the fire-pot, the end flanged walls of said frame forming the end supports for the grate when said grate is turned in either position, substantially as described.

11. In a stove, the combination of a casing having an opening therein, a fire-pot adjacent said opening, a grate horizontally and centrally pivoted in the opening in the casing, and adapted to be turned half-revolution to increase or decrease the fire-pot, and a door hinged to swing vertically to cover the opening, substantially as described.

12. A stove comprising a casing having an opening in one of its walls, a fire-pot, a receiving grate located in said opening, a door, a space being formed between the door and the front of the grate and between the top of the grate and the casing, establishing communication at all times between the space in front of the grate and the fire-pot, substantially as described.

698,681. NAIL-HOLDING ATTACHMENT FOR HAMMERS. EDNA L. CAMBER, Minneapolis, Minn. Filed Aug. 4, 1901. Serial No. 72,008. (No model.)

Claim.—1. A nail-holding attachment comprising the flat body *a* with hatched end spring-prongs *b* which prongs *b* overlap said body *a* and are adapted to clamp the head of a nail against said body, substantially as described.

2. A nail-holding attachment composed from a single piece of spring sheet metal and involving the body-strip *a* and hatched end prongs *b*, said body *a* having suitable notches and said prongs *b* overlapping said body *a* and adapted to press the head of the nail against said body-strip, substantially as described.

698,682. PROCESS OF MAKING ENRICHED CHARGE. LEO CAMBER, Lyons, France. Filed July 2, 1901. Serial No. 67,008. (No specimens.)

Claim.—The herein-described process consisting in mixing any-where water with paraffin and water, substantially as described.

698,683. ACETYLENE-GAS GENERATOR. EDWIN E. CAMBER, East Orange, N. J., assignor to Frank Fuller, trustee, New York, N. Y. Filed Feb. 2, 1901. Serial No. 44,444. (No model.)

Claim.—In acetylene-gas-generating apparatus the combination of a carrier-holder, a removable covering therefor, a water-supply conduit entering the holder, a gas-conduit leading out of the holder, a gas-valve, a single valve-piece common to the said conduits and the vent, and covering means in the form of one or more horizontally-swinging latches

operatively connected with the said valve, whereby displacement of the covering means effects the closure of the water and gas conduits and opening of the vent.

698,684. AEROPLANE. BLAS I. CORTES, Chicago, Ill. Filed July 14, 1901. Serial No. 65,002. (No model.)

Claim.—1. The combination, in an aeroplane, of a plurality of longitudinally-extending parallel sticks, triangular truss, consisting of a forward and a rear truss separated by an open space, cutting each stick, longitudinally-extending wings on the sides of the truss and containing an extension of one of the planes of the truss, a removable stick at right angles to the remaining sticks, each removable stick when in operative position maintaining the wings and the upper plane of the triangular truss in operative position, and a bridle attached to the remaining one of the parallel sticks and holding the remaining plane of the truss in operative position when a cord holding the aeroplane captive in the air is attached thereto; substantially as described.

2. The combination, in an aeroplane, of a plurality of parallel sticks, triangular truss cutting each stick, each truss positioned to obtain an open space between them, wings attached to two of the parallel sticks, means to obtain an upward bulging to the wings, respectively, when each wing are in an operative position, a removable stick at right angles to the parallel sticks and in contact with the ends thereof in the plane of the wings, each removable stick, when in operative position maintaining the wings and the plane of the truss between each wings in operative position, a bridle consisting of a cord attached to the one of the parallel sticks not adjacent to the wings, and a cord to hold the aeroplane captive attached to the bridle, each bridle proportioned to obtain a substantial right angle at the point of attachment thereto of the cord holding the aeroplane captive; substantially as described.

3. The combination, in an aeroplane, of a plurality of parallel sticks, triangular truss cutting each stick, each truss positioned to obtain an open space between them, wings attached to two of the parallel sticks, means to obtain an upward bulging to the wings, respectively, when each wings are in an operative position, cords attached, respectively, to the ends of the two of the parallel sticks to which the wings are attached and extending around the outer edges of the wings, a removable stick at right angles to the parallel sticks and in contact with the ends thereof in the plane of the wings, each removable stick, when in operative position, maintaining the wings and the plane of the truss between each wings in operative position, cords attached to the ends of the removable stick, when the same is in operative position, and to the sticks to which the wings are attached, respectively, and an additional cord attached to the ends of the removable stick and extending to the one of the parallel sticks not attached to the wings, a bridle attached to the last-named one of the parallel sticks, and a cord to hold the aeroplane captive attached to the bridle; substantially as described.

4. The combination in an aeroplane, of a plurality of parallel sticks, triangular truss cutting each stick, each truss positioned in double or open space between them, wings attached to two of the parallel sticks and a bridle attached to the remaining one of each parallel stick, means to hold the wings and the plane of the truss between the wings in an operative position and a cord attached to the bridle to hold the aeroplane.

obtained by the combination of truss and wings, *essence*; substantially as described.

5. The combination, in an aeroplane of a plurality of parallel struts, triangular trusses holding such struts, each truss positioned to sustain an open space between them, wings attached to two of the parallel struts, means to obtain an upward bulging in the wings, respectively, when each wing is in an operative position, a stick at right angles to the parallel struts and in contact with the ends thereof in the plane of the wings, each last-named stick, when in operative position maintaining the wings and the planes of the trusses between the wings in operative position, means to obtain a fallow in the forward part of the rear truss, whereby a fluttering movement in the several planes of the truss is obtained when the aeroplane is in the air, a bridle attached to the end of the parallel struts which is not adjacent to the wings, and a cord to hold the aeroplane operative attached to each bridle; substantially as described.

698,685. DRYING APPARATUS. HENRY DUBOIS, Paris, France.
Filed Feb. 6, 1901. Serial No. 45,191. (No model.)

Claim.—In a drying apparatus, the combination, with a rotatable casing having an inlet-opening for the gas and other products of combustion from the furnace, a discharge-opening for said gas, and a supply for the material to be dried, of a plurality of substantially parallel troughs disposed between said openings, said troughs having communication with their adjacent spaces alternately at their opposite ends, a rotary shaft arranged over each trough longitudinally thereof, and agitating baskets or shelves arranged on each shaft at the receiving end of the trough, said shelves or baskets each having side walls, and also a back wall disposed obliquely to the shaft, and an opening arranged adjacent the inner or rearward end of said back wall, substantially as described.

698,686. SHOEMAKER'S JACK. ALEXANDER T. DRAVER, New Haven, Conn., assignor of five-eighths to Charles H. Simmons and H. Henry Lambert, New Haven, Conn. Filed Mar. 28, 1901. Serial No. 52,593. (No model.)

Claim.—In a shoemaker's jack, the combination with the stand 1; of the rod 2 movable vertically therein; of a support-collar 10 adjustably secured upon said rod; a yoke-block 5 fixed to said rod and having a fixed plate 6 and a movable plate 7 connected therewith; a bracket 12 rotatably secured upon a post connected with said fixed plate 6 and clamped against movement between the said plates; an elbow 15 having a socket connection with said bracket, whereby the said elbow may be moved in a circular path about its socket connection; and a jack-plate 17 rotatably secured to said bracket and having suitable toe and heel supports thereon, all constructed and operating substantially as described.

698,686.

698,687. ELECTRIC METER. THOMAS DUNNAN, Port Wayne, Ind., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Feb. 7, 1902. Serial No. 600,355. (No model.)

Claim.—1. In an induction meter-meter, the combination with the series field-winding, of an armature in inductive relation therewith, a short field-winding also in inductive relation with said armature, said short field-winding comprising two coils and a transformer, the primary of said transformer being included in series with one of said pressure-coils and connected therewith across the circuit-mains, the secondary of said transformer being closed-circuited through the second pressure-coil, and a centrally-located core about which said pressure-coils are placed and affording the only path of magnetic material for the pressure lines of force to vary the magnetic flux due to said short-coil, threading the armature, an adjustment of said core toward the armature serving to deflect an increased number of lines of force through the armature, substantially as described.

2. In an induction meter-meter, the combination with a series field-winding, of an armature in inductive relation therewith, a short field-winding also in inductive relation with said armature, said short field-winding comprising two coils, a transformer, and means for varying the length of the magnetic circuit of said transformer, the primary of said transformer being included in series with one of said pressure-coils and connected therewith across the circuit-mains, the secondary of said transformer being closed-circuited through the second pressure-coil, and a centrally-located core about which said pressure-coils are placed, affording the only path of magnetic material for the pressure lines of force to vary the magnetic flux due to said short-coil, threading the armature, an adjustment of said core toward the armature serving to deflect an increased number of lines of force through said armature, substantially as described.

3. In an induction meter-meter, the combination with a series field-winding, of an armature in inductive relation therewith, a short field-winding also in inductive relation with said armature, said short field-winding comprising two coils, a transformer, and means for varying the length of said transformer, the primary of said transformer being included in series with one of said pressure-coils and connected therewith across the circuit-mains, the secondary of said transformer being closed-circuited through the second pressure-coil, a centrally-located core about which said pressure-coils are placed, affording the only path of magnetic material for the pressure lines of force, to vary the magnetic flux due to said short-coil, threading the armature, an adjustment of said core toward the armature serving to deflect an increased number of lines of force through said armature, and adjusting mechanism included in said primary and secondary transformer-circuits, substantially as described.

4. In an induction meter-meter, the combination with a series field-winding, of an armature in inductive relation therewith, a short field-winding also in inductive relation with said armature, said short field-winding comprising two coils, a transformer, and means for varying the length of said transformer, the primary of said transformer being included in series with one of said pressure-coils and connected therewith across the circuit-mains, the secondary of said transformer being closed-circuited through the second pressure-coil, a centrally-located core about which said pressure-coils are placed, affording the only path of magnetic material for the pressure lines of force to vary the magnetic flux due to said short-coil, threading the armature, an adjustment of said core toward the armature serving to deflect an increased number of lines of force through said armature, the said core being so proportioned that a large air-gap intervenes between the same and the said coils, and adjusting mechanism included in said primary and secondary transformer-circuits, substantially as described.

698,688. ELECTRIC METER. THOMAS DUNNAN, Port Wayne, Ind., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Apr. 11, 1902. Serial No. 677,118. (No model.)

Claim.—1. In a meter-meter, the combination with a series field-coil, of an armature in inductive relation therewith, a short field-coil also in inductive relation with said armature, adapted for inclusion with circuit-mains, an auxiliary short-coil reversely included with said mains, and means for deflecting more or less of lines of force of said auxiliary short-coil through said armature, substantially as described.

2. In a meter-meter, the combination with a series field-coil, of an armature in inductive relation therewith, a short field-coil also in inductive relation with said armature, adapted for inclusion with circuit-mains, an auxiliary short-coil reversely included with said mains, the said auxiliary short-coil being included with the mains in a reverse direction, and means for moving said auxiliary short-coil, thereby to vary the magnetic effect of the lines of force of said auxiliary short-coil on the armature, substantially as described.

3. The combination of a series coil; a volt or short coil; an auxiliary coil in multiple to said volt-coil; means for varying the axis of magnetization of said auxiliary coil out of parallelism with the axis of magnetization of the said volt-coil; and a revolvable metallic armature adapted to be actuated by the combined influence of the said series and volt and auxiliary coils.

4. In a meter-meter for alternating currents, a series coil or coils; a volt-coil; an impedance-coil in series with said volt-coil; an auxiliary coil in cooperative relation with said volt-coil; means for connecting said auxiliary coil in multiple to more or less of the convolutions of said volt-coil; and a closed revolvable metallic armature in inductive relation to said co-acting coils.

5. The combination with the pressure field-coil of an induction meter-meter, of a revolvable armature in inductive relation therewith, an adjustable iron core 24 to assist in overcoming the friction of the bearings by attracting intensity through the said armature the magnetic repulsion the electromotive force and produced by the said pressure field-coil, the said iron core having its longitudinal axis parallel with but eccentric to the said pressure field-coil, a second pressure field-coil receiving current independently of the said pressure field-coil, and means for affording said core a lateral adjustment for the purpose described.

6. In an induction meter-meter, a series field-coil, a volt or pressure coil, an auxiliary coil connected around the said pressure-coil, the convolutions of said auxiliary coil being wound in a direction opposite to or opposing the convolutions of said pressure-coil, an impedance-coil in series with said pressure-coil, a revolvable metallic armature in inductive relation to said series, pressure and auxiliary coils, and means for moving the said auxiliary coil thereby to vary the magnetic effect of the lines of force of said auxiliary short-coil on the armature, substantially as described.

7. In a meter-meter, the combination with a series field-coil, of an armature in inductive relation therewith, a short field-coil also in inductive relation with said armature, adapted for inclusion with circuit-mains, an auxiliary short-coil reversely included with said mains, means for deflecting more or less of lines of force of said auxiliary short-coil through said armature, and an impedance-coil in multiple series arrangement with said short-coil, substantially as described.

8. In an induction meter, the combination with series and short coils, of an armature in inductive relation therewith, a core associated with said short-coil for deflecting lines of force through said armature to induce eddy-currents therein for the purpose of overcoming friction of said armature, said core having its longitudinal axis parallel with said coil, and mounted on the side of the armature opposite to the side on which the pressure-coil is located, and means for varying the magnetic relation of said core to said coils, substantially as described.

9. In an electric meter, the combination with a current-winding, of a pressure-winding, an auxiliary pressure field-winding cooperatively associated with the said pressure-winding and included in short of turns of the said pressure-winding and being included therewith in a series-parallel connection with the source of current, means for effecting a relative displacement between the said pressure-windings, and a revolvable armature subjected to the action of said co-acting windings, substantially as described.

10. In an electric meter, the combination with a current-winding, of a pressure-winding, an auxiliary pressure field-winding cooperatively associated with the said pressure-winding and included in short of turns of the said pressure-winding and being included therewith in a series-parallel connection with the source of current, means for effecting a relative displacement between the said pressure-windings, a revolvable armature subjected to the action of said co-acting windings, and a phase-modifier associated with said series-parallel circuit, substantially as described.

11. In an electric meter, the combination with a current-winding, of a pressure-winding, an auxiliary pressure field-winding cooperatively associated with the said pressure-winding and included in short of turns of the said pressure-winding and being included therewith in a series-parallel connection with the source of current, means for effecting a relative displacement between the said pressure-windings, a revolvable armature subjected to the action of said co-acting windings, and a phase-modifier in series with said pressure-windings, substantially as described.

12. In an electric meter, the combination with a current-winding, of a pressure-winding, an auxiliary pressure field-winding cooperatively associated with the said pressure-winding and included in short of turns of the said pressure-winding and being included therewith in a series-parallel connection with the source of current, means for effecting a relative displacement between the said pressure-windings, a revolvable armature subjected to the action of said co-acting windings, and an impedance-coil in series with said pressure-windings.

13. An alternating-current electric meter provided with a current-winding, a pressure field-coil and an auxiliary coil in multiple with the pressure-coil, and adjustable in position with respect to said pressure-coil, substantially as described.

14. An alternating-current electric meter provided with a current-winding and two relatively adjustable pressure field-coils in parallel with each other and in series parallel with a source of current, substantially as described.

698,689. ELECTRIC METER. THOMAS DUNNAN, Port Wayne, Ind., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Apr. 11, 1902. Serial No. 677,111. (No model.)

Claim.—1. In an electric meter, a rotating device consisting of a pair or plurality of pairs of permanent magnets having the adjacent ends of the poles of each pair arranged in cooperative relation upon the same side of the revolvable disk armature as shown, a revolvable metallic disk armature in inductive relation to said rotating device, and means for adjusting said magnets to vary the density of the flux through said revolvable armature.

2. In a meter, the combination with a current-winding, of a series-

ring element actuated thereby, a retarding element movable with the measuring element, and permanent magnets, the unlike poles of the permanent magnets being opposed, each magnet offering a path for lines of force due to the other, the retarding element being interposed between the poles of each magnet, the unlike opposed poles being upon the same side of the retarding element, the current-winding serving to effect an increase in the magnetization of one permanent magnet corresponding to the decrease in the magnetization of the other permanent magnet effected by said winding, substantially as described.

3. In a meter, the combination with a current-winding, of a measuring element actuated thereby, a retarding element movable with the measuring element, permanent magnets, the unlike poles of the permanent magnets being opposed, each magnet offering a path for lines of force due to the other, the retarding element being interposed between the poles of each magnet, the unlike opposed poles being upon the same side of the retarding element, the current-winding serving to effect an increase in the magnetization of one permanent magnet corresponding to the decrease in the magnetization of the other permanent magnet effected by said winding, and means for effecting relative adjustment of the permanent magnets, substantially as described.

4. The combination with two field-coils, of means for modifying the phase of the magnetic field produced by one of them, means in circuit with said last-named coil for further modifying the phase of its magnetic field, and means for changing the number of turns of the last-named coil in action, whereby the relative effect of the two field energizing-coils is changed, substantially as described.

5. The combination with two field-coils, of means in circuit of one of said coils for modifying the phase of its magnetic field, and means for changing the number of turns of the latter coil in action, whereby the relative effect of the two field energizing-coils will be changed, substantially as described.

698,640. ELECTRIC METER. THOMAS DUBOIS, Fort Wayne, Ind., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed June 20, 1900. Serial No. 694,718. (No model.)

Claim.—1. In a multifrequency induction meter-meter, the combination with energizing-windings receiving current from the generator, of an armature in inductive relation therewith, and of an unexcited core in cooperative relation with one of the said energizing-windings for varying the magnetism due to the said coil to compensate for variation of frequency, substantially as described.

2. In an induction-meter, the combination with a revolvable armature, of a current-winding in inductive relation therewith, a pressure-winding also in inductive relation to said armature, and an unexcited magnetizable core for said pressure-winding for maintaining the magnetism due to the pressure-winding in quadrature with the pressure, substantially as described.

3. In a multifrequency induction meter-meter, the combination with current and pressure energizing windings, of an armature in inductive relation therewith, and an unexcited magnetizable core for said pressure-winding for varying the magnetism due to the said coil to compensate for variation of frequency, substantially as described.

4. In a multifrequency induction meter-meter, the combination with current and pressure energizing windings, of an armature in the form of a revolvable disk in inductive relation therewith, and an unexcited magnetizable core for said pressure-winding for varying the magnetism due to the said coil to compensate for variation of frequency, substantially as described.

5. In a multifrequency induction meter-meter, the combination with current and pressure energizing windings, of an armature in inductive relation therewith, said an unexcited magnetizable core for said pressure-winding for varying the magnetism due to the said coil to compensate for variation of frequency, the pressure-winding and said unexcited core being located upon the same side of the armature, substantially as described.

6. In a multifrequency induction meter-meter, the combination with current and pressure energizing windings, of an armature in inductive relation therewith, an unexcited magnetizable core for said pressure-winding for varying the magnetism due to the said coil to compensate for variation of frequency, and an impedance-coil in circuit with the pressure-winding, substantially as described.

7. In an induction meter-meter, the combination with a revolvable armature, of a current-winding in inductive relation therewith, a pressure-winding also in inductive relation to said armature, an unexcited magnetizable core for said pressure-winding for maintaining the magnetism due to the pressure-winding in quadrature with the pressure, and an impedance-coil in series with the pressure-winding, substantially as described.

8. In a multifrequency induction meter-meter, the combination with energizing-windings receiving current from the generator, of an armature in inductive relation therewith, said an unexcited adjustable core in cooperative relation with one of the said energizing-windings for varying the magnetism due to the said coil to compensate for variation of frequency, substantially as described.

9. In an induction-meter, the combination with a revolvable armature, of a current-winding in inductive relation therewith, a pressure-winding also in inductive relation to the said armature, and an unexcited magnetizable core for said pressure-winding for causing the requisite phase adjustment of the magnetism due to the pressure-winding, substantially as described.

10. In a multifrequency induction meter-meter, the combination with current and pressure energizing windings, of an armature in inductive relation therewith, and an adjustable unexcited magnetizable core for said pressure-winding for varying the magnetism due to the said coil to compensate for variation of frequency, substantially as described.

11. In an induction-meter, the combination with a revolvable armature, of a current-winding, a pressure winding in inductive relation to the said armature, and an unexcited magnetizable core for said pressure-winding for causing the requisite phase adjustment of the magnetism due to the pressure-winding, substantially as described.

12. In an induction-meter, the combination with a revolvable armature of a winding, a pressure-winding in inductive relation to the said armature, and an unexcited magnetizable core for said pressure-winding for causing the requisite phase adjustment of the magnetism due to the pressure-winding, substantially as described.

13. In a multifrequency induction meter-meter, the combination with current and pressure energizing windings, of an armature in inductive relation therewith, and an unexcited magnetizable steel core for said pressure-winding for varying the magnetism due to the said coil to compensate for variation of frequency, substantially as described.

698,641. ELECTRIC METER. THOMAS DUBOIS, Fort Wayne, Ind., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Aug. 1, 1900. Serial No. 697,999. (No model.)

Claim.—1. In a system of alternating-current distribution, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding being divided into two coils, an autotransformer having its winding included conductively in circuit with one of the pressure-coils and a portion of its winding included conductively in circuit with the remaining pressure-coil, and a measuring device subjected to the action of the field-windings, substantially as described.

2. In a system of alternating-current distribution, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding

being divided into two coils, an autotransformer having its winding included conductively in circuit with one of the pressure-coils and a portion of its winding included in a closed local circuit, the remaining pressure-coil being also included in circuit with the latter portion of the autotransformer, the coils of the pressure-winding being inductively related, and a measuring device subjected to the action of the field-windings, substantially as described.

3. In a system of transmission, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding being divided into two coils, an autotransformer having its winding included conductively in circuit with one of the pressure-coils and a portion of its winding included conductively in circuit with the remaining pressure-coil, and an armature in inductive relation to the said pressure-coils, substantially as described.

4. In a system of alternating-current distribution, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding being divided into two coils, an autotransformer having its winding included conductively in circuit with one of the pressure-coils and a portion of its winding included conductively in circuit with the remaining pressure-coil, a measuring device subjected to the action of the field-windings, and a phase-adjusting device also in circuit with the latter pressure-coil and the said portion of the autotransformer-winding, substantially as described.

5. In a system of alternating-current distribution, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding being divided into two coils, an autotransformer having its winding included conductively in circuit with one of the pressure-coils, the coils of the pressure-winding being inductively related, a measuring device subjected to the action of the field-windings, and a phase-adjusting device in circuit with the remaining pressure-coil and the secondary portion of the autotransformer-winding, substantially as described.

6. In a system of transmission, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding being divided into two coils, an autotransformer having its winding included conductively in circuit with one of the pressure-coils and a portion of its winding included conductively in circuit with the remaining pressure-coil, an armature in inductive relation to the said pressure-coils, and a phase-adjusting device also in circuit with the latter pressure-coil and the said portion of the autotransformer-winding, substantially as described.

7. In a system of alternating-current distribution, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding being divided into two coils, an autotransformer having its winding included conductively in circuit with one of the pressure-coils and a portion of its winding included conductively in circuit with the remaining pressure-coil, a measuring device subjected to the action of the field-windings, and a phase-adjusting device also in circuit with the latter pressure-coil and the said portion of the autotransformer-winding, substantially as described.

8. In a system of alternating-current distribution, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding being divided into two coils, an autotransformer having its winding included conductively in circuit with one of the pressure-coils, the coils of the pressure-winding being inductively related, a measuring device subjected to the action of the field-windings, and a phase-adjusting device in

circuit with the remaining pressure-coil and the secondary portion of the autotransformer-winding, substantially as described.

9. In a system of transmission, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding being divided into two inductively-related coils, an autotransformer having its winding included conductively in circuit with one of the pressure-coils and a portion of its winding included conductively in circuit with the remaining pressure-coil, an armature in inductive relation to the said pressure-coils, and a phase-adjusting device also in circuit with the latter pressure-coil and the said portion of the autotransformer-winding, substantially as described.

10. In a system of alternating-current distribution, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding being divided into two coils, an autotransformer having its winding included in circuit with one of the pressure-coils, and a portion of its winding included conductively in circuit with the remaining pressure-coil, and a measuring element, substantially as described.

11. In a system of alternating-current distribution, the combination with an alternating-current generator of current and pressure field-windings of a meter receiving current from said generator, the latter winding being divided into two coils, an autotransformer having its winding included in circuit with one of the pressure-coils, and a portion of its winding included in circuit with the said pressure-coil, and a measuring element, subjected to the action of the field-windings, substantially as described.

12. In a system of alternating-current distribution, the combination with the source of alternating current of two field-windings of a meter, one of said windings being divided into two coils, of an autotransformer having its winding included conductively in circuit with one of said coils and a portion of its winding included conductively in circuit with the other of said coils, and a measuring device subjected to the action of the field-windings, substantially as described.

13. In a system of alternating-current distribution, the combination with the source of alternating current of two field-windings of a meter, one of said windings being divided into two inductively-related coils, of an autotransformer having its winding included conductively in circuit with one of said coils and a portion of its winding included conductively in circuit with the other of said coils, and a measuring device subjected to the action of the field-windings, substantially as described.

14. In a system of alternating-current distribution, the combination with the source of alternating current of two field-windings of a meter, one of said windings being divided into two inductively-related coils, of an autotransformer having its winding included in circuit with one of said coils, and a portion of its winding included conductively in circuit with the other of said coils, and a measuring device subjected to the action of the field-windings, substantially as described.

15. In a system of alternating-current distribution, the combination with the source of alternating current of two field-windings of a meter, one of said windings being divided into two inductively-related coils, of an autotransformer having its winding included in circuit with one of said coils, and a portion of its winding included in circuit with the remaining coil, and a measuring device subjected to the action of the field-windings, substantially as described.

16. In a meter, the combination with current and pressure field-windings, the pressure field-winding being divided into two coils, of an impedance-winding in circuit with one of said coils, the remaining pressure field-coil being in a closed circuit with a metallically-continuous phase-modifying portion of the impedance-winding, substantially as described.

17. In a meter, the combination with current and pressure field-windings, the pressure field-winding being divided into two coils, of an impedance-winding in circuit with one of said coils, the remaining coil being in circuit with a metallically-continuous portion of the impedance-winding, substantially as described.

18. In a phase-modifying circuit, the combination with two field-coils, of an impedance-winding in circuit with one of said coils, a phase-modifying element being included between turns of the impedance-winding, the remaining coil being included in a closed circuit with the said phase-modifying element, substantially as described.

19. In a meter, the combination with current and pressure field-windings, the pressure field-winding being divided into two coils, of an impedance-winding in circuit with one of said coils, a phase-modifying element being included between turns of the impedance-winding, the remaining coil being included in a closed circuit with the said phase-modifying element, substantially as described.

698,642. ELECTRIC METER. THOMAS DUBOIS, Fort Wayne, Ind., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Aug. 12, 1900. Serial No. 698,000. (No model.)

Claim.—1. In a meter, the combination with current and pressure windings of an impedance-coil included in series with the pressure-winding and a phase-lagging coil in inductive relation with the aforesaid impedance-coil included in a closed circuit with a portion only of the pressure-winding, substantially as described.

2. In a meter, the combination with field-producing windings of an impedance-coil in series with one of the said windings and a phase-modifying coil included in a closed circuit with a portion only of the latter winding and in inductive relation to the said impedance-coil, substantially as described.

3. In a meter, the combination with current and pressure windings of an impedance-coil included in series with the pressure-winding, and a phase-lagging coil in inductive relation with the aforesaid impedance-coil included in a closed circuit with a portion only of the pressure-winding, substantially as described.

4. In a meter, the combination with field-producing windings of an impedance-coil in series with one of the said windings, and a phase-modifying coil included in a closed circuit with a portion only of the latter winding and in inductive relation to the said impedance-coil, substantially as described.

5. In a meter, the combination with current and pressure windings of an impedance-coil included in series with the pressure-winding, and a coil in inductive relation with the impedance-coil included in a closed circuit with the said turns of the pressure-winding, independently of the impedance-coil, substantially as described.

6. In a meter, the combination with field-producing windings of an impedance-coil included in series with the pressure-winding, and a coil in inductive relation with the impedance-coil included in a closed circuit with the said turns, independently of the impedance-coil, substantially as described.

7. In a meter, the combination with current and pressure windings of an impedance-coil included in series with the pressure-winding, and a coil in inductive relation with the impedance-coil included in a closed circuit with the said turns of the pressure-winding, independently of the impedance-coil, substantially as described.

8. In a meter, the combination with field-producing windings of an impedance-coil included in series with the pressure-winding, and a coil in inductive relation with the impedance-coil included in a closed circuit with the said turns, independently of the impedance-coil, substantially as described.

698,648. ELECTRIC METER. THOMAS DUNN, Port Wayne, Ind., assignor to the Thomson & Hubbs Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Aug. 24, 1899. Serial No. 698,648. (No model.)

Claim.—1. The combination in an induction meter-motor of a series field-coil; a combined pressure magnetic field and impedance device comprising a laminated iron core with a low-reluctance air-gap and magnetizing-coils mounted upon both sides of said air-gap and upon the adjacent poles of said iron core forming said air-gap; a metallic disk armature revolvable between the poles of and in the air-gap of said iron core; a secondary circuit receiving current by induction from the said combined pressure magnetic field and impedance device; a variable resistance in series with said secondary circuit; a retarding magnetic field governing the revolutions of said armature; and means for registering the revolutions of said armature.

2. The combination in an induction meter-motor, of a combined pressure magnetic field and impedance device provided with magnetizing-coils mounted thereon, a revolvable armature inductively associated with said device, a secondary circuit receiving current by induction from said device, means for varying the current in said secondary circuit, series field-coils also inductively associated with said revolvable armature, the magnetic influence of said series field-coils and said pressure magnetic field-coils acting upon the armature in different areas, substantially as described.

3. The combination in an induction meter-motor, of series field-coils, a combined pressure magnetic field and impedance device, provided with magnetizing-coils mounted thereon, a revolvable armature inductively associated with said device and said series field-coils, a secondary circuit receiving current by induction from said device, a variable resistance in series with said secondary circuit, and a retarding magnetic field governing the revolutions of said armature, the said series field-coils and said combined pressure magnetic field-coils acting upon the armature in different areas, substantially as described.

4. The combination in an induction meter-motor, of series field-coils, a combined pressure magnetic field and impedance device comprising an iron core with a low-reluctance air-gap, provided with magnetizing-coils mounted thereon, a revolvable armature inductively associated with said device and said series field-coils, a secondary circuit receiving current by induction from said device, a variable resistance in series with said secondary circuit, and a retarding magnetic field governing the revolutions of said armature, the said series field-coils and said combined pressure magnetic field-coils acting upon the armature in different areas, substantially as described.

698,644. ELECTRIC METER. THOMAS DUNN, Port Wayne, Ind., assignor to the Thomson & Hubbs Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 14, 1899. Serial No. 698,644. (No model.)

Claim.—1. An electric meter comprising a revolvable armature, series and volt coils for actuating the armature, an impedance-coil connected in series with the volt-coil in a shunt-circuit across the line, and a resistance connected in a parallel shunt-circuit leading around the impedance-coil and connected to the volt-coil between its ends, substantially as described.

2. In an induction meter-motor, the combination of a series coil; a revolvable metallic armature; a volt-coil; an impedance-coil in series with the said volt-coil; a resistance shunted around the said impedance-coil and a portion of the said volt-coil, so as to form; and a portion of the said volt-coil that is traversed by the current flowing through the said impedance-coil and the said resistance, for the purpose described.

3. In an induction meter-motor the combination of a series coil; a revolvable armature; a volt-coil; an impedance-coil; a shunt-circuit including the said impedance-coil and the said volt-coil; a second shunt-circuit including a resistance and a portion of the said volt-coil for obtaining a resultant magnetic field that is in quadrature with the electromotive force at the terminals of the said shunt-circuit.

4. In an induction meter-motor the combination of supply-means; a series coil; a volt-coil having a portion of its convolutions opening the balance of its turns; an impedance-coil in series with the said volt-coil; a resistance in series with a portion of the convolutions of the said volt-coil, the said resistance and said portion of said volt-coil being connected in multiple to the said supply-means; and a revolvable armature in inductive relation to the said series and volt coils.

5. In an induction meter-motor the combination of a series coil; a revolvable metallic armature; a volt-coil; an impedance-coil in series with the said volt-coil; a shunt-circuit including a variable resistance and a portion of the said volt-coil; the said portion of said volt-coil being preferably wound to establish a counter magnetomotive force to the balance of the turns comprising the said volt-coil, as described.

6. In an induction meter-motor the combination of a series coil; a volt-coil of the class described; an impedance-coil in series with said volt-coil; a shunt-circuit comprising and including a variable resistance and a portion of the said volt-coil as described; a revolvable armature in inductive relation to the said series and volt coils; and the herein-described means of varying the number of turns of the said volt-coil employed in series with said variable resistance.

7. In a meter, the combination with an armature, of windings for actuating the same, turns of an impedance-coil connected in series with one of the windings, and a resistance connected at one terminal between the terminals of the winding in shunt with the impedance, whereby turns of the winding are disposed upon each side of the said resistance-terminal, the said resistance being included in a closed circuit with a portion of the latter field-winding and the impedance-winding turns.

8. In a meter, the combination with an armature, of current and pressure windings for actuating the same, turns of an impedance-coil connected in series with one of the windings, and a resistance connected at one terminal between the terminals of the pressure-winding, whereby turns of the pressure-winding are disposed upon each side of the said resistance-terminal, the said resistance being included in a closed circuit with a portion of the pressure-winding and the impedance-winding turns.

9. In a meter, the combination with an armature, of windings for actuating the same, a phase-modifying device connected in series with one of the windings, and a second phase-modifying device connected at one terminal between the terminals of the winding in shunt with the first phase-modifying device, whereby turns of said winding are disposed upon each side of the said terminal of the second phase-modifying device, the latter device being included in a closed circuit with a portion of said field-winding and the first phase-modifying device, substantially as described.

698,645. ELECTRIC METER. THOMAS DUNN, Port Wayne, Ind., assignor to the Thomson & Hubbs Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Feb. 8, 1899. Serial No. 704,751. (No model.)

Claim.—1. The combination with two field-windings of a meter, of means in shunt of one of said windings for adjusting the phase of the magnetism due thereto, a primary ϕ in series with the latter winding, and included therewith across the work-circuit, and a secondary circuit in inductive relation to said primary winding, one terminal of the phase-adjusting means being interposed between the said winding and the primary, while the other terminal of said means is connected with the remaining terminal of the said winding, substantially as described.

2. The combination with two field-windings of a meter, of means in shunt of one of said windings for adjusting the phase of the magnetism due thereto, a primary ϕ in series with the latter winding and placed across the work-circuit, and a secondary circuit in inductive relation to the said primary winding, one terminal of the phase-adjusting means being interposed between the said winding and the primary, while the other terminal of said means is connected with the remaining terminal of the said winding, substantially as described.

3. The combination with two field-windings of a meter, of means in shunt of one of said windings for adjusting the phase of the magnetism due thereto, a primary ϕ in series with the latter winding and placed across the work-circuit, and a closed secondary circuit in inductive relation to said primary winding, one terminal of the phase-adjusting means being interposed between the said winding and the primary, while the other terminal of said means is connected with the remaining terminal of the said winding, substantially as described.

698,646. ELECTRIC METER. THOMAS DUNN, Port Wayne, Ind., assignor to the Thomson & Hubbs Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Feb. 23, 1899. Serial No. 704,694. (No model.)

Claim.—1. In a system of distribution, the combination with an alternating-current generator, of a meter comprising a revolvable armature, a series field-coil in inductive relation with said armature, and a pressure field-coil for producing a field displaced two hundred and seventy degrees from the pressure, divided into two coils, one of said coils receiving its current from the secondary of a transformer, substantially as described.

2. In an induction meter, the combination of a current-coil, an armature in inductive relation to said current-coil, and a pressure-winding comprising two coils, one of said coils receiving its current from the secondary of a transformer coupled across the circuit-mains thereby to produce a phase difference of two hundred and seventy degrees between the field of said pressure-winding and the pressure, substantially as described.

3. In a system of distribution, comprising transmission-mains and a generator, of a meter adapted for association with said mains, comprising a revolvable armature, a series field-coil in inductive relation therewith, a shunt-winding also in inductive relation to said armature, said shunt-winding being divided into two coils, one of said coils receiving its current directly from the transmission-mains, the second coil receiving its current from the secondary of the transformer included with the transmission-mains and being adapted to produce a stronger field than the first aforesaid coil thereby to secure a phase displacement of two hundred and seventy degrees between the field of said pressure-winding and the improved pressure, substantially as described.

4. In a meter, the combination with current and pressure windings for producing magnetic fields differing in phase, said pressure-winding being divided into two coils, one of said coils receiving its current from the source of supply, of a transformer receiving its current also from said source, the other pressure coil being included in the secondary circuit of said transformer and being adapted to create a stronger magnetism than the first aforesaid pressure-coil, substantially as described.

5. In a meter, the combination with an alternating-current generator, of a meter having current and pressure windings for producing magnetic fields differing in phase, the pressure-winding being divided into two coils, one of said coils being inductively connected with the source of current, of a transformer having its primary inductively connected with the same source of current and its secondary included in a circuit with the other of said coils, said coils being in inductive relation with each other, the last aforesaid coil being adapted to create a stronger magnetic field than the first aforesaid pressure-coil, thereby to secure a phase displacement of two hundred and seventy degrees between the magnetic field due to each pressure-winding and the improved pressure, and an armature for said meter in inductive relation with the meter-windings, substantially as described.

6. In a meter, the combination with a revolvable armature, of a series coil in inductive relation therewith, a shunt-winding also in inductive relation with said armature divided into two coils, one of said coils receiving its current from the secondary of a transformer, said coil being adapted to create a stronger magnetic field than the first aforesaid pressure-coil, substantially as described.

7. In a meter, the combination with a revolvable armature, of a series coil in inductive relation therewith, a pressure-winding comprising two coils, one of said coils being adapted for inclusion with the source of supply, the second pressure-coil being adapted for inclusion with the secondary of a transformer included with the source of supply, the last aforesaid coil being adapted to create a stronger magnetic field than the first aforesaid coil, thereby to secure a phase displacement of two hundred and seventy degrees between the field due to the pressure-winding and the improved pressure, substantially as described.

8. In a meter, the combination with a revolvable armature, of a series coil in inductive relation therewith, a pressure-winding comprising two coils, one of said coils being adapted for inclusion with the source of supply, the second pressure-coil being adapted for inclusion with the secondary of a transformer included with the source of supply, the last aforesaid coil being adapted to create a stronger magnetic field than the first aforesaid coil, thereby to secure a phase displacement of two hundred and seventy degrees between the field due to the pressure-winding and the improved pressure, substantially as described.

9. In a meter, the combination with a revolvable armature, of a series coil in inductive relation therewith, a pressure-winding comprising two coils, one of said coils being adapted for inclusion with the source of supply, the second pressure-coil being adapted for inclusion with the secondary of a transformer included with the source of supply, the last aforesaid coil being adapted to create a stronger magnetic field than the first aforesaid coil, thereby to secure a phase displacement of two hundred and seventy degrees between the field due to the pressure-winding and the improved pressure, substantially as described.

698,647. ELECTRIC METER. THOMAS DUNN, Port Wayne, Ind., assignor to the Thomson & Hubbs Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Apr. 22, 1899. Serial No. 714,912. (No model.)

Claim.—1. An indicating electric meter provided with an armature comprising an outer shell of non-magnetic metal, and an inner lining of magnetic metal, and coils mounted on said armature and connected in the circuit to be measured.

2. In an electric meter, the combination with an armature-winding, of an outer shell of non-magnetic metal fixed with relation to the said winding, and an inner lining of magnetic metal, substantially as described.

3. In an electric meter, the combination with an armature-winding, of an outer shell of non-magnetic metal fixed with relation to the said winding, and an inner body of magnetic metal also fixed with relation to the said winding, substantially as described.

698,647.

698,648. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed May 24, 1906. Serial No. 718,082. (No model.)

Claim.—1. The combination with a main circuit, of a transformer having its primary coil connected in series in said main circuit and its secondary coil connected in shunt to its primary coil, and an energizing coil connected in series in said secondary circuit.

2. The combination with a series transformer having its secondary connected in shunt to its primary coil, of a measuring instrument or meter provided with an energizing coil connected in series in said secondary circuit.

3. The combination with a main circuit of a transformer having its primary coil connected in series in said main circuit and its secondary coil connected in shunt to its primary coil, an energizing coil connected in series in the secondary circuit, and means for adjustingly varying the relative proportions of the shunt and secondary coil.

4. The combination with a main circuit, of a transformer having its primary coil connected in series in said main circuit and its secondary coil connected in shunt to its primary coil, an energizing coil connected in series in the secondary circuit, and means for adjustingly varying the length of the secondary coil.

5. The combination with a primary circuit, of means for producing an induced current from the primary current, means for deriving a shunt-current from said primary current, and a meter or measuring instrument energized by the combined action of said induced and shunt currents.

6. In a system of distribution, the combination with a source of alternating current, of a winding receiving current therefrom, a second winding inductively related to the first and included in a shunt-circuit about the same, and a meter having a winding included in the said shunt, substantially as described.

7. In a system of distribution, the combination with a transformer having its primary of few turns and included entirely in the circuit, and having its secondary of a larger number of turns and included in a shunt-circuit about the primary, of a meter having an energizing-winding included in said shunt in series with the secondary, substantially as described.

8. In a system of distribution, the combination with a transformer having its primary of few turns and included entirely in the circuit, and having its secondary of a larger number of turns and included in a shunt-

circuit of said primary, of a wattmeter having a current field-producing winding included in the shunt-circuit and in series with the secondary, said meter also having a pressure field-winding, substantially as described.

9. In a system of electrical distribution, the combination with a source of alternating current, of a transformer having its primary-winding receiving current from the said source, the secondary of the transformer being included in a shunt-circuit about the said primary, and a meter having a winding included in the said shunt-circuit, substantially as described.

10. The combination with an inducting-coil, of an induced coil in inductive relation therewith included in shunt about the said inducting-coil, and a wattmeter having one of its windings included in the said shunt-circuit, substantially as described.

11. The combination with a transformer having its secondary included in a shunt-circuit about its primary, of a wattmeter having a winding included in the said shunt-circuit, substantially as described.

12. The combination with an inducting-coil, of an induced coil in inductive relation therewith included in shunt about the said inducting-coil, and a wattmeter having its current-winding included in the said shunt-circuit, substantially as described.

13. The combination with a transformer having its secondary included in a shunt-circuit about its primary, of a wattmeter having its current-winding included in the said shunt-circuit, substantially as described.

698,649. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed July 10, 1906. Serial No. 728,585. (No model.)

Claim.—1. An electric meter provided with an armature, series and volt coils inductively actuating the armature, an impedance-coil connected in the shunt-circuit with the volt-coil, and a secondary coil placed in inductive relation to the impedance-coil and having its terminals connected with the terminals of the volt-coil, the said secondary coil being directly connected in multiple with the winding in shunt with the impedance-coil, substantially as described.

2. An electric meter provided with an armature, series and volt coils for inductively actuating the armature, an impedance-coil connected in the shunt-circuit with the volt-coil, a secondary coil placed in inductive relation to the impedance-coil and having its terminals connected with the terminals of the volt-coil, and a closed-circuit adjusting-coil placed in inductive relation to the impedance and secondary coils.

3. An electric meter provided with an armature, series and volt coils inductively actuating the armature, an impedance-coil connected in a shunt-circuit with a volt-coil, a secondary coil placed in inductive relation to the impedance-coil, and having its terminals connected with the terminals of the volt-coil, the secondary coil being connected directly in multiple with the volt-coil in shunt with the impedance-coil, substantially as described.

4. The combination with the work-circuit, of an electric meter provided with an armature A, an energizing-coil B connected in series in said work-circuit, an energizing-coil C connected in shunt across the line, an impedance-coil D inserted in said shunt-circuit, a secondary coil E placed in inductive relation to the impedance-coil D having its terminals connected with the terminals of the coil C, the secondary coil being directly connected in multiple with the energizing-coil in shunt with the impedance-coil, a measuring device F and a magnetic drag G, substantially as described.

5. An electric meter provided with an armature, two windings for effecting the operation of the armature, an impedance-coil connected in series with one of the windings, and a secondary coil placed in inductive relation to the impedance-coil and directly connected in multiple with the field-winding in series with the impedance-coil, substantially as described.

6. An electric meter provided with an armature, series and volt windings for effecting the operation of the armature, an impedance-coil connected in series with the volt-winding and a secondary coil placed in inductive relation to the impedance-coil and having its terminals connected with the terminals of the volt-winding, the secondary coil being directly connected in multiple with the winding in series with the impedance-coil, substantially as described.

698,650. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Aug. 1, 1906. Serial No. 728,586. (No model.)

Claim.—1. An electric meter provided with an armature, a series coil connected in series in the work-circuit, a volt-coil connected in two shunt-circuits between the main leads of the work-circuit, and impedance-coils inserted in each of said shunt-circuits, substantially as described.

2. An electric meter provided with an armature, a series field-coil connected in series in the work-circuit, a volt field-coil connected in two shunt-circuits between the main leads of the work-circuit, and impedance-coils inserted in each of said shunt-circuits and arranged in inductive relation to each other, substantially as described.

3. An electric meter provided with an armature, a series field-coil connected in series in the work-circuit, a volt field-coil connected in two shunt-circuits between the main leads of the work-circuit, impedance-coils inserted in each of said shunt-circuits, and a starting-coil inserted in one of said shunt-circuits, substantially as described.

4. In a meter, the combination with current and pressure windings, the pressure-windings being subdivided into two coils having a common terminal, an impedance-coil connecting the said common terminal with one side of a distribution-circuit, and a second impedance-coil connecting the remaining terminal of a pressure-coil with the other side of the distribution-circuit while the remaining terminal of the remaining pressure-coil is also connected with the latter side of the distribution-circuit, substantially as described.

5. In a meter, the combination with current and pressure windings, the pressure-windings being subdivided into two coils having a common terminal, an impedance-coil connecting the said common terminal with one side of a distribution-circuit, and a second impedance-coil connecting the remaining terminal of a pressure-coil with the other side of the distribution-circuit while the remaining terminal of the remaining pressure-coil is also connected with the latter side of the distribution-circuit, the impedance-coils being inductively related, substantially as described.

6. In a meter, the combination with current and pressure windings, the pressure-windings being subdivided into two coils having a common terminal, an impedance-coil connecting the said common terminal with one side of a distribution-circuit, a second impedance-coil connecting the remaining terminal of a pressure-coil with the other side of the distribution-circuit while the remaining terminal of the remaining pressure-coil is also connected with the latter side of the distribution-circuit, and a phase-modifying device connected in shunt of the distribution-main, substantially as described.

7. In a meter, the combination with current and pressure windings, the pressure-windings being subdivided into two coils having a common terminal, an impedance-coil connecting the said common terminal with one side of a distribution-circuit, a second impedance-coil connecting the remaining terminal of a pressure-coil with the other side of the distribution-circuit while the remaining terminal of the remaining pressure-coil is also connected with the latter side of the distribution-circuit, the impedance-coils being inductively related, and a phase-modifying device connected in shunt of the distribution-main, substantially as described.

698,651. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Aug. 21, 1906. Renewed Oct. 2, 1907. Serial No. 77,592. (No model.)

Claim.—1. The combination with a main circuit, of a transformer having its primary coil connected in series in said main circuit and its secondary coil connected in shunt to its primary coil, and an energizing-coil also connected in shunt to the primary coil and in parallel with the secondary circuit.

2. The combination with a series transformer having its secondary connected in shunt to its primary circuit, of a measuring instrument or meter provided with an energizing-coil connected in shunt to the primary circuit and in parallel with the secondary circuit.

3. The combination with the main circuit, of a transformer having its primary coil connected in series with the main circuit, and its second-

ary coil connected in shunt to its primary coil, an energizing-coil also connected in shunt to the primary coil and in parallel with the secondary coil, and means for adjustingly varying the relative proportions of the shunt circuit.

4. The combination with a series transformer having its secondary connected in shunt to its primary circuit, of a measuring instrument or meter provided with an energizing-coil also connected in shunt to the primary circuit and in parallel with the secondary circuit, and means for adjustingly varying the number of turns in the secondary coil of the transformer.

5. The combination with a series transformer having its secondary connected in shunt to its primary circuit, of a measuring instrument or meter provided with an energizing-coil also connected in shunt to the primary circuit of the transformer and in parallel with the secondary circuit, and means for adjustingly varying the resistance of said secondary circuit.

698,652. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Aug. 22, 1906. Serial No. 728,587. (No model.)

Claim.—1. The combination, with the armature, series and volt field-coils, and an impedance-coil in series with the volt field-coil in a shunt-circuit across the line, of a resistance connected in said shunt-circuit in parallel with the field-coil and including the turns of the impedance-coil.

2. The combination, with the armature, series and volt field-coils, and an impedance-coil in series with the volt field-coil in a shunt-circuit across the line, of a resistance connected in said shunt-circuit in parallel with the volt field-coil and forming therewith a shunt circuit including a portion of the turns of the impedance-coil.

3. The combination, with the armature, series and volt field-coils, and an impedance-coil in series with the volt field-coil in a shunt-circuit across the line, of a resistance connected in said shunt-circuit in parallel with the volt field-coil and forming therewith a shunt circuit including a portion of the turns of the impedance-coil, and means for varying the number of the included turns.

4. The combination, with the armature, series and volt field-coils, and an impedance-coil connected in series with each terminal of the volt field-coil in a shunt-circuit across the line, of a resistance connecting said impedance-coils in parallel with the volt field-coil and including a portion of the turns of each.

5. The combination, with an armature, of field-windings therefor, an impedance-coil in shunt with one of the windings, a resistance in shunt of one of the windings including turns of the impedance-coil and forming therewith a shunt circuit, substantially as described.

698,653. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Aug. 22, 1906. Renewed Oct. 2, 1907. Serial No. 77,591. (No model.)

Claims.—1. In a direct-current motor, the combination with the field portion of the motor, of an armature, a frame for supporting the armature and field portion, and means for effecting the universal adjustment of the field portion readily to effect the proper relative disposition of the field portion and armature, substantially as described.

2. In a direct-current motor, the combination with an armature, of a field-coil adjustably and detachably secured in front of the armature, and a frame for the motor for supporting the armature and field-coil, substantially as described.

3. In a direct-current motor, the combination with an armature, of two field-coils, one located in front of the armature and the other to the rear thereof, the rear field-coil being adjustable with relation to the armature, substantially as described.

4. In a direct-current motor, the combination with an armature, of the two field-coils, one located in front of the armature and the other to the rear thereof, the said coils being adjustable with relation to the armature, substantially as described.

5. In a direct-current motor, the combination with an armature, of two field-coils, one located in front of the armature and the other to the rear thereof, the said field-coils being adjustable with relation to the armature and to each other, substantially as described.

6. In a direct-current motor, the combination with an armature, of two field-coils, one located in front of the armature and the other to the rear thereof, the said field-coils being mounted to have swinging adjustment.

7. In a direct-current motor, the combination with an armature, of a horizontally-adjustable field portion thereof, and frame portions for supporting the armature and field portion, substantially as described.

8. In a direct-current motor, the combination with an armature, of a field portion thereof adjustable in a vertical plane, and frame portions for supporting the armature and the field portion, substantially as described.

9. In a direct-current motor, the combination with a frame thereof, of a vertically-adjustable horizontally-extending base secured to the frame, field-coils mounted upon the base, and an armature located between the field-coils, substantially as described.

10. In a direct-current motor, the combination with a frame thereof, of a vertically-adjustable horizontally-extending base secured to the frame, field-coils mounted upon the base, an armature located between the field-coils, and means for supporting the field-coils upon the base, permitting of the horizontal adjustment of the field-coils upon the base, substantially as described.

11. The combination with the vertical back portion of the frame of a motor, of a support 23 projecting forwardly therefrom, a base 18 also projecting forward from the vertical back portion of the frame, a bearing carried by the base, an armature spindle or shaft journaled at its lower end in said bearing, an armature upon the spindle, a commutator disk provided upon the said spindle, an upper bearing for the spindle carried by the support 23 intermediate between the forward and rear ends of the support, and a counting-train engaging the spindle and mounted above the

commutator upon the forward end of the support 23 in front of the upper bearing for the spindle, substantially as described.

12. In a direct-current motor, the combination with an armature mounted to rotate in a horizontal plane, of a commutator therefor, two horizontally-disposed commutator-brushes each spirally formed at one end and adapted to engage the commutator at the other end, vertically-disposed spindles 26, to which the brushes are secured at their spiral ends, vertical brush-holders 27 provided with bases for receiving the said spindles, the spindles being rotatable in said bases, whereby the adjustment of the brushes may readily be effected, and clamping-screws 29 passed through the sides of the brush-holders transversely and curving to engage the spindles 26 to cause the same in the position in which they have been rotated, substantially as described.

13. In a direct-current motor, the combination with an armature mounted to rotate in a horizontal plane, of a commutator therefor, two horizontally-disposed commutator-brushes, each spirally formed at one end and adapted to engage the commutator at the other end, vertically-disposed spindles 26 to which the brushes are secured at their spiral ends, vertical brush-holders 27 provided with elongated bases for receiving the said spindles, the spindles being rotatable and movable vertically in said bases, whereby the rotary and vertical adjustment of the brushes may readily be effected, and clamping-screws 29 passing through the sides of the brush-holders transversely and curving to engage the spindles 26 to secure the same in the position to which they have been rotated and vertically placed, substantially as described.

698,654. ALTERNATING-CURRENT METER. THOMAS DUNBAR, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Aug. 26, 1899. Serial No. 724,694. (No model.)

Claims.—1. In a voltmeter for polyphase circuits, the combination with a plurality of rotatable armatures mounted upon a common shaft, of series coils, one in inductive relation with each of said armatures, each series coil being adapted for induction with an independent electric circuit; a shunt-coil across the main circuit, in inductive relation with each armature, a second shunt-coil also in inductive relation with each of said armatures and each of the shunt-coils, the second shunt-coils receiving current from the shunt-coils associated therewith by induction, means for regulating the degree of induction, a variable resistance inserted with each of said second shunt-coils, whereby the magnetic effect due to the shunt-coils are caused to differ in phase ninety degrees from the impressed pressure of the respective circuits, a single counting-train operated by the said shaft, a rotating-disk mounted upon said shaft, said single initial starting-coil 31 associated with one of the said armatures to compensate for friction and other losses, said single initial starting-coil operating in a dual capacity to compensate for the said losses of each of said armatures.

698,655. ALTERNATING-CURRENT MOTOR-METER. THOMAS DUNBAR, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 12, 1899. Renewed Oct. 14, 1901. Serial No. 73,655. (No model.)

Claims.—1. In a device of the class described, the combination with an armature of a series and a shunt coil in inductive relation therewith,

and means for creating a counter electromotive force in said shunt-coil whereby the magnetic effect of said shunt-winding is advanced in phase to uniformly with that of the impressed electromotive force of the circuit, said armature moving proportionally to the magnetic field due to the said field and shunt-coils, substantially as described.

2. In a device of the class described, the combination with an armature of a series and a shunt winding in inductive relation therewith, a non-inductive resistance in series with said shunt-winding and a subsidiary circuit in shunt to said shunt-winding and including adjustable means for producing a counter electromotive force in said shunt-winding, said armature moving proportionally to the magnetic field due to the said field and shunt windings, substantially as described.

3. In a device of the class described, the combination with an armature of a series and a shunt winding in inductive relation therewith, a non-inductive resistance in series with said shunt-winding, a subsidiary circuit in shunt to said shunt-winding, and adjustable means for inducting more or less of said shunt-winding in said subsidiary circuit, said armature moving proportionally to the magnetic field due to the said field and shunt windings, substantially as described.

4. In an induction motor-meter, the combination with a rotatable armature of a series and a shunt winding in inductive relation therewith, a resistance-coil in series with said shunt-winding, a subsidiary circuit in shunt to said shunt-winding, adjustable means for producing a counter electromotive force in said shunt-winding, a rotating device associated with said armature and means for indicating the movement of said armature, said armature moving proportionally to the magnetic field due to the said field and shunt windings.

5. In a device of the class described, the combination with an armature, of a series and a shunt coil in inductive relation therewith, means for creating a counter electromotive force in said shunt-coil whereby the magnetic effect of said shunt-winding is advanced in phase to uniformly with that of the impressed electromotive force of the circuit, and means for indicating the magnetic effect of the lag of the current behind said electromotive force, substantially as described.

6. In a device of the class described, the combination with an armature of a series and a shunt winding in inductive relation therewith, a non-inductive resistance in series with said shunt-winding, a subsidiary circuit in shunt to said shunt-winding and including adjustable means for producing a counter electromotive force in said shunt-winding, and means for indicating the magnetic effect of the lag of the current behind said electromotive force, substantially as described.

698,656. INDUCTION MOTOR-METER. THOMAS DUNBAR, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 12, 1899. Renewed Dec. 12, 1901. Serial No. 64,656. (No model.)

Claims.—1. In a device of the class described, the combination with a rotatable element, of a series and a shunt winding in inductive relation therewith, a resistance-coil in series with the said shunt-winding, and an auxiliary circuit adapted to modify the magnetic effect of said shunt-winding whereby the magnetism of said shunt-winding may be brought into uniformity with the phase of the impressed electromotive force of the circuit.

2. In a device of the class described, the combination with a rotatable element, of a series and a shunt winding in inductive relation therewith, and an auxiliary winding adapted to modify the magnetic effect of

said shunt-winding and to bring it in phase with the impressed electromotive force of the circuit, substantially as described.

3. In a device of the class described, the combination with an armature, of a series and a shunt winding in inductive relation therewith, a non-inductive resistance in series with said shunt-winding, and an auxiliary winding adapted to modify the magnetic effect of said shunt-winding and to bring it in phase with the impressed electromotive force in the circuit, substantially as described.

4. In a device of the class described, the combination with a rotatable element, of a series and a shunt winding in inductive relation therewith, a non-inductive resistance in series with said shunt-winding, an auxiliary shunt-coil, an impedance-coil in said auxiliary shunt-coil, and a shunt-winding also in said auxiliary circuit and adapted to modify the magnetic effect of said main shunt-winding and to bring it in phase with the impressed electromotive force of the circuit, substantially as described.

5. In a device of the class described, the combination with a rotatable element, of a series and a shunt winding in inductive relation therewith, an auxiliary shunt-winding adapted to carry current in opposition to said main shunt-winding, and means for adjusting the combined magnetic effects of the two shunt-windings whereby the resultant magnetic effect thereof upon the rotatable element is brought in phase with the impressed electromotive force of the circuit, substantially as described.

6. In a device of the class described, the combination with a rotatable element, of a series and a shunt winding in inductive relation therewith, a non-inductive resistance in series with said shunt-winding, an auxiliary shunt-winding carrying current in opposition to that in said main shunt-winding, and an adjustable impedance-coil in series with said auxiliary shunt-winding whereby the combined magnetic effects of the main and auxiliary shunt-windings may be brought in phase with the impressed electromotive force of the circuit, substantially as described.

7. In a device of the class described, the combination with a rotatable element, of a series and a shunt winding in inductive relation therewith, a non-inductive resistance in series with the said shunt-winding, an auxiliary shunt-winding adapted to carry current in opposition to that in said main shunt-winding, an adjustable impedance-coil, and an adjustable non-inductive resistance in series with said auxiliary shunt-winding whereby the combined magnetic effects of the main and auxiliary shunt-windings may be brought in phase with the impressed electromotive force of the circuit, substantially as described.

8. In an induction motor-meter of the class described, the combination with the armature a, the series winding c, shunt-winding d, of the non-inductive resistance e in shunt with said shunt-winding d, the auxiliary shunt-winding g, carrying current in opposition to that in winding d, and an adjustable impedance-coil f, whereby the magnetic field due to the pressure-winding is maintained in phase with the pressure, substantially as described.

9. In an induction motor-meter of the class described, the combination with the armature a, the series winding c, the shunt-winding d, of the non-inductive resistance e in shunt with said shunt-winding d, the auxiliary shunt-winding g, carrying current in opposition to that in winding d, an adjustable impedance-coil f, and the adjustable resistance e, whereby the magnetic field due to the pressure-winding is maintained in phase with the pressure, substantially as described.

698,657. INDUCTION MOTOR-METER. THOMAS DUNBAR, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 12, 1899. Renewed Dec. 12, 1901. Serial No. 64,657. (No model.)

Claims.—1. In a device of the class described, the combination with an armature, of a series and a shunt winding in inductive relation therewith, a secondary circuit in inductive relation with said armature and also with said shunt-winding, and means for producing a resultant magnetism of said shunt-winding in phase with the impressed electromotive force of the circuit, substantially as described.

2. In a device of the class described, the combination with a rotatable element, of a series and a shunt-winding in inductive relation therewith,

with, a resistance-coil in series with said shunt-winding, a secondary circuit including a winding, and means for producing therein electromotive force whereby a magnetic field is produced in phase with the electromotive force of the main circuit, substantially as described.

3. In a device of the class described, the combination with a reversible structure, of a series and a shunt winding in inductive relation therewith, a resistance-coil in series with said shunt-winding, a secondary circuit receiving current from the circuit including said shunt-winding, and means for producing and maintaining a magnetic field in phase with the impressed electromotive force of the main circuit, substantially as described.

4. In an induction motor-meter, the combination with a reversible structure, of a series and a shunt winding in inductive relation therewith, a resistance-coil in series with said shunt-winding, a secondary circuit receiving current by induction from the circuit including said shunt-winding, and an impedance-coil in said secondary circuit whereby the phase of the magnetism of the shunt field-winding is maintained in phase with the impressed electromotive force of the circuit, substantially as described.

5. In a device of the class described, the combination with a reversible structure, of a series and a shunt winding in inductive relation therewith, a secondary circuit receiving current by induction from the circuit including said shunt-winding, a winding in said secondary circuit also in inductive relation with said structure, and means for carrying and maintaining the magnetism of said shunt field-winding in phase with the impressed electromotive force of the main circuit and for exerting upon the movable element a torque varying as the sine of the angle of lag of current of the main circuit behind its impressed electromotive force, substantially as described.

6. In an induction motor-meter, the combination with an armature, of a series and a shunt winding in inductive relation therewith, a resistance-coil in series with said shunt-winding, a secondary circuit receiving its current by induction, a winding included in said secondary circuit and in inductive relation with said shunt-winding, means for adjusting the phase of the current in said secondary circuit to bring the resultant magnetism of the pressure-winding into phase with the impressed electromotive force of the circuit, means for exerting upon the movable element a torque varying as the sine of the angle of lag of current behind the electromotive force, and means for indicating the variation of said torque, substantially as described.

7. The combination in an induction motor-meter, with a reversible structure 1, of a series winding 11, the shunt-winding 2, the non-inductive resistance 7 in circuit with said shunt-winding 2, the secondary winding 4, whereby the field due to the pressure-winding is maintained in phase with the pressure, the adjustable impedance-coil 6, and the adjustable resistance 5 in series with said secondary winding 4, substantially as and for the purpose specified.

698,658. MOTOR-METER. THOMAS BROWN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 25, 1898. Renewed Jan. 6, 1902. Serial No. 24,425. (No model.)

Claim.—1. In a polyphase-current induction motor-meter, the combination with two motor members, each comprising series and pressure windings for receiving current from the circuit, and each having an armature in inductive relation with the said windings, of transformers having their primaries connected in parallel in circuits including said series windings, and auxiliary pressure-windings in the secondary circuits of said transformers adapted to modify the magnetism of the said pressure-wind-

ings to bring the same into quadrature with the impressed electromotive force of the circuit including said series winding, a pressure-winding of one motor member receiving current from the circuit supplying current to the current-winding of the other motor member, substantially as described.

2. In a polyphase-current induction motor-meter, the combination with two or more armatures coupled together, of a current and a pressure-winding in inductive relation with each of said armatures, each pressure-winding receiving current from the circuit applying the current-winding associated with the other pressure-winding, the current in each pressure-winding lagging beyond ninety degrees with relation to the pressure in the circuit including its associated current-winding, and a second pressure-winding associated with each of the abovesaid pressure-windings and carrying current lagging less than ninety degrees with relation to the pressure in the circuit including its associated current-winding, whereby the magnetism due to said pressure-windings is brought in quadrature with the electromotive force of the circuit including said current-winding, substantially as described.

3. In a device of the class described, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, transformers having their primaries connected in parallel in the circuit including said current-windings, a second pressure-winding in the secondary circuit of each of said transformers and adjusting resistance in series with said last-named windings, whereby the magnitude of the current in said secondary circuits may be modified and the magnetism of the pressure-windings be brought in quadrature with the impressed electromotive force of the circuit including said current-coil, a pressure-winding of one motor member receiving current from the circuit supplying current to the current-winding of the other motor member, substantially as described.

4. In a polyphase-current induction motor-meter, the combination with two motive sets of windings each comprising a current and a pressure winding each pressure-winding receiving current from the circuit applying the current-winding associated with the other pressure-winding, the current in each pressure-winding lagging beyond ninety degrees with relation to the pressure in the circuit including its associated current-winding, and a second winding associated with each of said pressure-windings and carrying current lagging less than ninety degrees with relation to the pressure in the circuit including its associated current-winding, whereby the magnetism due to said pressure-windings is brought in quadrature with the electromotive force of the circuit including said current-winding, and a movable element subjected to the action of said motive sets of windings, substantially as described.

5. In a polyphase-current induction motor-meter, the combination with two motive sets of windings each comprising a current and a pressure winding, each pressure-winding receiving current from the circuit applying the current-winding associated with the other pressure winding, the current in each pressure-winding lagging beyond ninety degrees with relation to the pressure in the circuit including its associated current-winding, and a second winding associated with each of said pressure-windings and carrying current lagging less than ninety degrees with relation to the pressure in the circuit including its associated current-winding, and means included in series with each of said second pressure-windings for adjusting the magnetism due thereto, whereby the magnetism due to said pressure-windings is brought in quadrature with the electromotive force of the circuit including said current-winding, and a movable element subjected to the action of said motive sets of windings, substantially as described.

6. In a device of the class described, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, said pressure-winding being connected with a circuit carrying a current with a phase ninety degrees behind that of the circuit including the current-winding, a transformer having its primary connected in shunt of a circuit including the current-winding, and a winding in circuit with the secondary of said transformer and adapted to maintain the magnetism of the pressure-winding in quadrature with the electromotive force of the circuit including the current-winding, substantially as described.

7. In a device of the class described, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, said pressure-winding being connected with a circuit carrying a current with a phase ninety degrees behind that of the circuit including the current-winding, a transformer having its primary connected in shunt of a circuit including the current-winding, and a winding in circuit with the secondary of said transformer and adapted to maintain the magnetism of the pressure-winding in quadrature with the electromotive force of the circuit including the current-winding, substantially as described.

8. In a device of the class described, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, said pressure-winding being connected with a circuit carrying a current with a phase ninety degrees behind that of the circuit including the current-winding, and a transformer having its primary connected in shunt of a circuit including the current-winding, and a winding in circuit with the secondary of said transformer and adapted to maintain the magnetism of the pressure-winding in quadrature with the electromotive force of the circuit including the current-winding, substantially as described.

former having its primary connected in shunt of a circuit including the current-winding, and a winding and an adjustable resistance in shunt with the secondary of said transformer and adapted to maintain the magnetism of the pressure-winding in quadrature with the electromotive force of the circuit including the current-winding, substantially as described.

9. In a device of the class described, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, said pressure-winding being connected with a circuit different from that including the current-winding, and means extending to the pressure-winding circuit for carrying and maintaining a lag of ninety degrees between the magnetism of the pressure-winding and the electromotive force of the circuit including the current-coil, substantially as described.

10. In a device of the class described, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, said pressure-winding being connected with a circuit different from that including the current-winding, a transformer having its primary connected in shunt of a circuit including the current-winding, and a winding in the circuit with the secondary of the said transformer and associated with the said pressure-winding, whereby the resultant magnetism of pressure-winding is maintained in quadrature with the electromotive force of the circuit including the current-winding, substantially as described.

11. In a polyphase-current meter, the combination with two motor members, each having current and pressure windings for association with the circuit, of transformers having their primaries connected in parallel in circuits including said current-windings, and auxiliary pressure-windings in the secondary circuits of said transformers adapted to secure the desired modification of the phase of the magnetism due to the pressure-windings, the said pressure-windings receiving current from circuits respectively different from those supplying their associated auxiliary pressure-windings, substantially as described.

12. In a device of the class described, the combination with current-windings, of pressure-windings each included in a circuit different from that including the corresponding current-winding, means extending to the pressure-winding circuits for carrying and maintaining the desired phase relation between the magnetism of the pressure-winding and the electromotive force of the circuit including the corresponding current-winding, and a movable element subject to the action of said windings, substantially as described.

13. In a device of the class described, the combination with current-windings, of pressure-windings, each included in a circuit different from that including the corresponding current-winding, a transformer associated with each pressure-winding, the primary of each transformer receiving current from the circuit including the current-winding corresponding to the pressure-winding associated with the transformer, and a secondary pressure-winding in each secondary transformer-circuit each of the first abovesaid pressure-windings being operatively associated with a secondary pressure-winding whereby the desired modification of the phase of the magnetism due to the pressure-windings may be secured, substantially as described.

14. In a meter, the combination with current and pressure windings thereof, a transformer, and an auxiliary pressure-winding operatively associated with the abovesaid pressure-winding to modify the phase of the magnetism due thereto and receiving current from the secondary of said transformer, the first abovesaid pressure-winding receiving current from a circuit different from that supplying current to the primary of said transformer, substantially as described.

698,659. MOTOR-METER. THOMAS BROWN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 25, 1898. Renewed Jan. 6, 1902. Serial No. 24,426. (No model.)

Claim.—1. In an induction motor-meter the combination with an armature of the current-winding in inductive relation therewith, a pressure-winding of relatively high self-induction also in inductive relation with said armature, a second pressure-winding associated with said first pressure-winding but having relatively small self-induction, the connections of the said two pressure-windings with the circuit being reversed, an impedance-coil having two windings, one of relatively large number of turns

connected in series with said first pressure-coil, and the other of a less number of turns connected in shunt with said second pressure-coil and an adjustable resistance also in shunt with said second pressure-coil, substantially as and for the purpose specified.

2. In an induction motor-meter, the combination with the armature, of a current-winding in inductive relation therewith, two pressure-windings having reversed connections also in inductive relation with said armature, and an impedance-coil having two windings each included in circuit with one of said pressure-windings independently of the other, whereby the magnetism representing the electromotive force may be maintained in quadrature with the electromotive force, substantially as described.

3. In a device of the class described, the combination with an armature of a current-winding in inductive relation therewith, a pressure-winding having large self-induction also in inductive relation with said armature, a second pressure-winding having relatively small self-induction, said pressure-windings having their connections reversed, and an impedance-coil having two windings each included in circuit with one of said pressure-windings independently of the other, whereby the magnetism representing the electromotive force may be maintained in quadrature with the electromotive force, substantially as described.

4. In an induction motor-meter, the combination with an armature of the current-winding in inductive relation therewith, a pressure-winding also in inductive relation with said armature, a second pressure-winding having small self-induction with relation to said first pressure-winding and having its connections reversed in direction to that of the first pressure-winding, an impedance-coil having windings each in circuit with a pressure-winding independently of the other, and an adjustable resistance in circuit with said second pressure-winding whereby the magnetism of the pressure-winding is maintained in quadrature with the electromotive force of the circuit including the series winding.

5. In an induction motor-meter the combination with an armature, of a current and two pressure windings in inductive relation therewith, an impedance-coil having interacting windings each included in circuit with a pressure-winding independently of the other and a means included in circuit with one of said pressure-windings, whereby the magnetism of the pressure-field may be maintained in quadrature with the electromotive force of the working circuit, substantially as described.

6. In a device of the class described, the combination with the reversible structure 5 of the current-coil 4 in inductive relation therewith, pressure-coil 6 connected in shunt with the main circuit also in inductive relation therewith, a secondary pressure-coil 18 associated with said pressure-coil 6 and having in connection with the main circuit reversed with respect to those of the first pressure-coil, the impedance-coil 9 having the windings 9' and 9'' connected in circuit respectively with the pressure-coils 6 and 18, the adjustable resistance 10 connected in circuit with said pressure-coil 18, the retarding-magnet 21 in inductive relation with the armature, and the counting-train 20, adapted to be operated by said reversible structure, substantially as and for the purpose set forth.

7. In an induction motor-meter, the combination with the armature of a current-winding in inductive relation therewith, two pressure-windings also in inductive relation therewith and two interacting impedance-windings receiving current independently of each other, each pressure-winding being operatively associated with an impedance-winding whereby the desired phase relation between the field due to said pressure-windings and the impressed electromotive force is secured, substantially as described.

8. In an induction motor-meter, the combination with the armature of a current-winding in inductive relation therewith, two pressure-windings having relatively large and small self-induction also in inductive relation therewith and two interacting impedance-windings receiving current independently of each other, each pressure-winding being operatively associated with an impedance-winding whereby the desired phase relation between the field due to said pressure-windings and the impressed electromotive force is secured, substantially as described.

9. In a meter, the combination with a current-winding, of two pressure-windings, and two interacting impedance-windings receiving current independently of each other each pressure-winding being operatively associated with an impedance-winding, whereby the desired phase relation between the field due to said pressure-windings and the impressed electromotive force is secured, substantially as described.

10. A meter having current and pressure field-windings, in combination with interacting impedance-windings receiving current independently of each other and operatively associated with the pressure field portion of the meter, whereby the desired phase relation between the pressure-field and the impressed electromotive force may be secured, substantially as described.

11. In an alternating-current motor-meter, the combination with a current field-winding, of two pressure field-windings and an impedance-coil having interacting windings, each included in circuit with a pressure-winding of the meter independently of the other, substantially as described.

698,660. POLYPHASE MOTOR-METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 28, 1899. Renewed Nov. 18, 1901. Serial No. 55,692. (No model.)

Claim.—1. In a device of the class described, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, said pressure-winding being connected with a circuit different from that including said series winding, an impedance-cell in circuit with said pressure-winding, and means for securing and maintaining a lag of ninety degrees between the magnetism of said pressure-winding and the impressed electromotive force of the circuit including the current-winding, substantially as described.

2. In a device of the class described, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, said pressure-winding being connected with a circuit carrying a current lagging in phase ninety degrees behind the electromotive force of the circuit including the series winding, an impedance-cell in circuit with said pressure-winding, and means for securing and maintaining a lag of ninety degrees between the magnetism of said pressure-winding and the electromotive force of the circuit including the current-winding, substantially as described.

3. In a polyphase-current induction meter-meter, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, said pressure-winding being connected with a circuit different from that including the current-winding, and means for producing a counter electromotive force in the circuit including said pressure-winding whereby the magnetic effect of said winding is maintained in quadrature with the impressed electromotive force of the circuit including said current-winding, substantially as described.

4. In a polyphase induction meter-meter, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, said pressure-winding being connected with a circuit different from that including the current-winding, an impedance-cell in circuit with said pressure-winding, an auxiliary circuit in shunt with said current-winding and adapted to produce a counter electromotive force in the circuit of said pressure-winding, a winding on the core of said impedance-cell and included in said auxiliary circuit, and means for adjusting the phase of said auxiliary circuit, whereby the magnetic effect of said pressure-winding is maintained in quadrature with the impressed electromotive force of the circuit including said current-winding, substantially as described.

5. In a device of the class described, the combination with two or more armatures coupled together, of a current and a pressure winding in inductive relation with each of said armatures, said pressure-winding being connected with a circuit different from that including said current-winding, an impedance-cell in circuit with said pressure-winding, and means for securing and maintaining a displacement of ninety degrees between the magnetism of said pressure-winding and the impressed electromotive force of the circuit including the current-winding, substantially as described.

6. In a polyphase-current meter, the combination with two sets of motor-windings each including current and pressure windings, the pressure-winding of each set receiving current from the circuit applying the current-winding of the other set, and two inducting impedance-windings associated with each pressure-winding, one receiving current from the system of distribution, and the other electrically associated with its pressure-winding, the latter pressure-winding also receiving current independent-

only of the inducting impedance-windings, substantially as described.

7. In a polyphase-current meter, the combination with two sets of motor-windings each including current and pressure windings, the pressure-winding of each member receiving current from a different circuit than that including its associated current-winding, and two inducting impedance-windings associated with each pressure-winding, one receiving current from the circuit including the associated current-winding and the other in series with its associated pressure-winding, substantially as described.

8. In a polyphase meter, the combination with current and pressure windings, and inducting impedance-windings receiving current independent of each other from different circuits one being electrically associated with the pressure-winding, substantially as described.

9. In a polyphase meter, the combination with current and pressure windings, and inducting impedance-windings receiving current independent of each other from different circuits one being included in series with the pressure-winding, substantially as described.

698,661. MOTOR-METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 28, 1899. Renewed Nov. 18, 1901. Serial No. 55,619. (No model.)

Claim.—1. In a direct-current motor-meter, the combination with a hollow armature having windings, of a commutator having its segments connected with the said windings, a core of magnetic material extending within the armature, a field-winding, and a measuring device operated by the armature, substantially as described.

2. In a direct-current motor, the combination with a hollow rotatable armature having windings, of a commutator having its segments connected with the said windings, means for establishing and maintaining a field comprising two members, namely: a field-winding and a magnetic core for increasing the magnetic density of the field in which the armature is disposed, one of the said members being located within the interior of the armature, and a measuring device operated by the armature, substantially as described.

3. In a direct-current motor, the combination with a hollow rotatable armature having windings, of a commutator having its segments connected with the said windings, a stationary-mounted core of magnetic material extending within the armature, a field-winding, and a measuring device operated by the armature, substantially as described.

4. In a direct-current motor, the combination with a hollow rotatable armature having windings, of a commutator having its segments connected with the said windings, means for establishing and maintaining a field comprising two members, namely: a fixed field-winding and a fixed magnetic core for increasing the magnetic density of the field in which the armature is included, one of the said members being located within the interior of the armature, and a measuring device operated by the armature, substantially as described.

5. In a direct-current motor-meter, the combination with a rotatable

armature having windings and provided with a hollow interior, of a stationary core of magnetic material extending within the interior of the armature, a field-winding upon the exterior of the armature, and a measuring device operated by the armature, substantially as described.

6. In a direct-current motor-meter, the combination with a hollow rotatable armature provided with windings adapted for inclusion across the working conductors, of a commutator therefor, brushes for engagement with the commutator, a stationary core extending within the armature, a field-winding upon the exterior of the armature adapted for inclusion in series with the working circuit, and a measuring device operated by the armature, substantially as described.

7. In a direct-current motor-meter, the combination with a hollow rotatable armature provided with windings adapted for inclusion across the working conductors, of a commutator therefor, brushes for engagement with the commutator, a stationary magnetic core projecting within the interior of the armature, a field-winding upon the exterior of the armature adapted for inclusion in shunt with the working conductors, a core for the series field-winding embracing the armature, and a measuring device operated by the armature, substantially as described.

8. In a direct-current motor-meter, the combination with a rotatable armature in the form of a hollow cylinder provided with windings adapted for inclusion in a bridge conductor across the working conductors, of a commutator for the armature, commutator-brushes for engagement with the commutator, a stationary magnetic core projecting within the interior of the armature, a field-winding upon the exterior of the armature adapted for inclusion in shunt with the working conductors, a core for the series field-winding embracing the armature, and a measuring device operated by the armature, substantially as described.

9. In a direct-current motor-meter, the combination with a rotatable armature in the form of a hollow cylinder provided with windings adapted for inclusion in a bridge conductor across the working conductors, of a commutator for the armature, commutator-brushes for engagement with the commutator, a stationary magnetic core projecting within the interior of the armature, a field-winding upon the exterior of the armature adapted for inclusion in shunt with the working conductors, a core for the series field-winding embracing the armature, and a measuring device operated by the armature, substantially as described.

10. An armature for direct-current motor, comprising a fixed or corrugated support, and armature-windings maintained in position by the corrugations in the support, substantially as described.

11. An armature for direct-current motor, comprising a corrugated cylindrical support, and windings adapted to be maintained in place upon the said support by the corrugations therein, substantially as described.

12. An armature for direct-current motor, comprising a corrugated cylindrical support, and windings adapted to be maintained in place upon the said support by the corrugations therein, the lower portion of the cylindrical support being provided with a rim for supporting the lower ends of the armature-coils, substantially as described.

13. An armature for direct-current motor, comprising a corrugated support, and armature-coils separately formed and maintained in place by the corrugations in the said support, substantially as described.

14. An armature for direct-current motor, comprising a corrugated cylindrical support and armature-coils, separately formed, and secured in place by their engagement with the corrugations in the said support, substantially as described.

15. An armature for direct-current motor, comprising a corrugated cylindrical support having an outwardly-extending flange, or rim, surrounding the same, and armature-coils, separately formed, secured in place by their engagements with the corrugations in the support and resting at their lower ends upon the said rim, substantially as described.

16. In a direct-current wattmeter, the combination with a series field-winding, of an armature having its coils arranged to form a hollow cylinder, a commutator connected with the coils of the armature, commutator-brushes for the commutator for including the armature in bridge between the main of a working circuit, and a measuring device operated by the armature, substantially as described.

17. In a direct-current wattmeter, the combination with a field-winding adapted for inclusion in series with the working circuit, of a rotatable armature whose coils are arranged to form a hollow cylinder disposed within the field created by the series field-winding, a commutator for the armature, commutator-brushes for including the armature in the bridge across the working conductors, and a measuring device operated by the armature, substantially as described.

18. As a new article of manufacture, a commutator-brush for direct-current motor, spirally formed at the end that is to be secured, and curved throughout a portion of its length, substantially as described.

19. As a new article of manufacture, a commutator-brush for direct-current motor, constructed of strip metal, spirally formed at the end that is to be secured, and curved throughout a portion of its length, substantially as described.

698,662. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 28, 1899. Renewed Nov. 18, 1901. Serial No. 55,618. (No model.)

Claim.—1. An electric meter for two-phase systems comprising a pair of rotatable armatures, series and volt coils for both armatures, the series coils of the two armatures being connected in the separate circuits of the system, and the volt-coils in each case being connected between the leads of that circuit in which the other field-coils are connected, subsidiary volt-coils applied to the main volt-coils of each armature and connected in shunt between the leads of the circuit in which the series coils of that armature are connected, and means for registering the armature rotation.

2. An electric meter for two-phase systems comprising a pair of armatures secured upon a common spindle, series coils connected in series in one of the circuits and mounted in inductive relation to one of the armatures, other series coils connected in series in the other circuit and mounted in inductive relation to the other armature, volt-coils mounted in inductive relation to the first armature and connected in a shunt between the leads of that circuit in which the series coils of the second armature are connected, volt-coils mounted in inductive relation to the second armature and connected in shunt between the leads of that circuit in which the field-coils of the first armature are connected, subsidiary volt-coils mounted in inductive relation to the main volt-coils of each armature, and subsidiary coils for each armature being connected in shunt between the leads of the circuit in which the series coils of that armature are connected, and a registering mechanism operatively connected with said spindle.

3. An electric meter comprising a pair of rotatable armatures, series and volt coils for both armatures, and means for registering the armature rotation, the series coils of the two armatures being connected in the separate circuits of the system and the volt-coils of each armature being connected in shunt between the leads of the circuit in which the series coils of the other armature are connected, and a compensating-coil adjustably mounted in proximity to one armature and connected in the shunt-circuit with the volt-coils of the other armature.

4. An electric meter for two-phase systems comprising a pair of armatures secured upon a common spindle, series coils connected in series in one of the circuits and mounted in inductive relation to one of the armatures, other series coils connected in series in the other circuit and mounted in inductive relation to the other armature, volt-coils mounted in inductive relation to the first armature and connected in a shunt between the leads of that circuit in which the series coils of the second armature are connected, volt-coils mounted in inductive relation to the second armature and connected in shunt between the leads of that circuit in which the field-coils of the first armature are connected, subsidiary volt-coils mounted in inductive relation to the main volt-coils of each armature, and subsidiary coils for each armature being connected in shunt between the leads of the circuit in which the series coils of that armature are connected, and a compensating-coil adjustably mounted in proximity to one armature and connected in the shunt-circuit with the volt-coils of the other armature, and a registering mechanism operatively connected with said spindle.

698,663. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Sept. 28, 1899. Renewed Oct. 28, 1901. Serial No. 55,521. (No model.)

Claim.—1. In an electric motor for two-phase system, comprising a pair of reversible armatures, series and volt coils for both armatures, the series coils of the two armatures being connected in the separate circuits of the system, and the volt-coil of each armature being connected between the leads of that circuit in which the field-coil of the other armature is connected, and subsidiary volt-coils applied to the main volt-coils and energized by secondary currents induced by primary circuits connected between the leads of both of the main circuits of the system, substantially as described.

2. An electric motor for two-phase system, comprising a pair of reversible armatures, series and volt coils for both armatures, the series coils of the two armatures being connected in separate circuits of the system and the volt-coil of each armature being connected between the leads of that circuit in which the field-coil of the other armature is connected, and subsidiary volt-coils applied to the main volt-coils and connected in the secondary circuits of a transformer having primary circuits connected in shunt between the leads of both of the main circuits of the system, substantially as described.

3. An electric motor for two-phase system, comprising a pair of reversible armatures, series and volt coils for both armatures, the series coils of the two armatures being connected in the separate circuits of the system, and the volt-coil of each armature being connected between the leads of that circuit in which the field-coil of the other armature is connected, subsidiary volt-coils applied to the main volt-coils and connected in the secondary circuits of a transformer having primary circuits connected in shunt between the leads of both of the main circuits of the system, and adjustable resistances connected in circuit with said subsidiary coils, substantially as described.

698,664. MOTOR-METER. THOMAS DUBOIS, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Oct. 11, 1900. Renewed Jan. 9, 1902. Serial No. 98,495. (No model.)

Claim.—1. In an induction motor-meter, the combination with a movable element, of a series and a pressure field-winding in inductive relation therewith, and an artificial neutral resistance adapted for interposition between the mains of the circuit connected with said pressure field-winding, independently of the latter winding and adapted in cooperation with the said pressure field-winding to maintain the magnetic

field thereof in quadrature with the electromotive force of the circuit including said series winding, substantially as described.

2. In a motor-meter the combination with current and pressure windings for effecting the movement of the movable element of the meter, of an artificial neutral resistance adapted for interposition between the mains of the circuit independently of said pressure-winding, and in cooperation with said pressure-winding serving to maintain the desired phase relation between the pressure-field and the electromotive force of the working circuit, substantially as described.

3. The combination with a three-phase system of alternating-current distribution, of a motor-meter having current and pressure windings, and an artificial neutral resistance connected directly between the sides of the system independently of the pressure-winding and cooperating with the pressure-winding to maintain the desired phase relation between the pressure-field and the electromotive force of the working circuit, substantially as described.

4. The combination with a three-phase system of alternating-current distribution, of a motor-meter having current and pressure windings, and an artificial neutral resistance having three branches interposed between the sides of the three branches of the system independently of the pressure-winding and cooperating with the pressure-winding to maintain the desired phase relation between the pressure-field and the electromotive force of the working circuit, substantially as described.

5. In a motor-meter, the combination with current and pressure windings for effecting the movement of the movable element of the meter, of an artificial neutral resistance adapted for interposition between the mains of the circuit independently of said pressure-winding, and in cooperation with said pressure-winding serving to maintain the desired phase relation between the pressure-field and the electromotive force of the working circuit, and an armature in inductive relation with said pressure and current windings, substantially as described.

6. The combination with a three-phase system of alternating-current distribution, of a motor-meter having current and pressure windings, and an artificial neutral resistance connected directly between the sides of the system independently of the pressure-winding and cooperating with the pressure-winding to maintain the desired phase relation between the pressure-field and the electromotive force of the working circuit, and an armature in inductive relation with said pressure and current windings, substantially as described.

7. The combination with a three-phase system of alternating-current distribution, of a motor-meter having current and pressure windings, and an artificial neutral resistance having three branches interposed between the sides of the three branches of the system independently of the pressure-winding, and cooperating with the pressure-winding to maintain the desired phase relation between the pressure-field and the electromotive force of the working circuit, and an armature in inductive relation with said pressure and current windings, substantially as described.

8. In a motor-meter, the combination with current and pressure windings for effecting the movement of the movable element of the meter, of an artificial neutral resistance adapted for interposition between the mains of the circuit independently of said pressure-winding, and in cooperation with said pressure-winding serving to maintain the desired phase relation between the pressure-field and the electromotive force of the working circuit, said pressure-winding receiving its current through said resistance, substantially as described.

9. The combination with a three-phase system of alternating-current distribution, of a motor-meter having current and pressure windings, and an artificial neutral resistance connected directly between the sides of the system independently of the pressure-winding and cooperating with the pressure-winding to maintain the desired phase relation between the pressure-field and the electromotive force of the working circuit, said pressure-winding receiving its current through said resistance, substantially as described.

10. The combination with a three-phase system of alternating-current distribution, of a motor-meter having current and pressure windings, and an artificial neutral resistance having three branches interposed between the sides of the three branches of the system independently of the pressure-winding and cooperating with the pressure-winding to maintain the desired phase relation between the pressure-field and the electromotive force of the working circuit, said pressure-winding receiving its current through said resistance substantially as described.

11. In a three-phase meter, the combination with current and pressure windings, the latter being divided into two inductively-related coils, of a star-connected resistance receiving current independently of the pressure-winding, each coil of which is connected across a branch of the star-connected resistance, substantially as described.

12. In a three-phase meter, the combination with a movable element, of a current field-winding in inductive relation therewith, a pressure-coil also in inductive relation therewith, a second pressure-coil also in inductive relation with said movable element and adapted to have its phase re-

lative lie between the impressed electromotive force of the circuit including the current-winding and that of the current in said first pressure-coil, and a star-connected artificial resistance receiving current from the work-shunt independently of the pressure-winding, each pressure-coil being connected across a branch of the said artificial resistance, substantially as described.

13. In a three-phase meter, the combination with current and pressure windings, the latter being divided into two coils, of a star-connected resistance receiving current independently of the pressure-winding, each coil of which is connected across a branch of the star-connected resistance, substantially as described.

14. In a motor-meter, the combination with current and pressure windings, the pressure-winding being divided into two inductively-related coils included in circuit with each other, of phase-modifying resistance having branches in parallel with said pressure-coils, substantially as described.

15. In a three-phase meter, the combination with current and pressure windings, the latter being divided into two inductively-related coils, of a star-connected resistance receiving current independently of the pressure-winding, each coil of which is connected across a branch of the star-connected resistance, substantially as described.

16. In a motor-meter, the combination with current and pressure windings, the pressure-winding being divided into coils in circuit with each other, of phase-modifying resistance having branches in parallel with said pressure-coils, substantially as described.

698,665. ALTERNATING CURRENT METER. THOMAS DUBOIS, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 4, 1900. Renewed Dec. 14, 1901. Serial No. 98,496. (No model.)

Claim.—1. In an alternating-current commutated meter-meter, the combination with a movable measuring element, of means for exerting thereon a torque varying substantially as the sine of the angle of lag between the current and pressure, a portion of said means comprising a movable armature for actuating said element and having a field-producing winding adapted for inclusion in circuit, and a commutator for including said winding, substantially as described.

2. In an alternating-current commutated meter-meter, the combination with a pressure-winding provided with means for maintaining the magnetism due thereto substantially in quadrature with the pressure, a current-winding for producing a second field, and a commutator for conveying current to one of said windings, substantially as described.

3. In an alternating-current meter-meter, the combination with a movable measuring element, of means for exerting thereon a torque varying substantially as the sine of the angle of lag between the current and pressure, a portion of said means comprising a movable armature for actuating said element and having a field-producing winding for inclusion in circuit, substantially as described.

4. In an alternating-current meter-meter, the combination with means for exerting and maintaining a field substantially in quadrature with the pressure, of means for exerting and maintaining a second field substantially in phase with the current, one of said means comprising a movable armature having a field-producing winding, substantially as described.

5. In an alternating-current commutated meter-meter, the combination with means for exerting and maintaining a field substantially in quadrature with the pressure, of means for exerting and maintaining a second field substantially in phase with the current, one of said means comprising

ing a movable armature having a field-producing winding, and a commutator for including the armature in circuit, substantially as described.

6. In an alternating-current meter-meter, the combination with a current-winding, of a pressure-winding provided with means for maintaining the field due thereto substantially in quadrature with the pressure, and a movable measuring element, one of the said windings being movable to actuate said element, substantially as described.

7. In an alternating-current commutated meter-meter, the combination with a current-winding, of a pressure-winding provided with means for maintaining the field due thereto substantially in quadrature with the pressure, a movable measuring element, one of the said windings being movable to actuate said element, and a commutator for including the latter winding in circuit, substantially as described.

8. In an alternating-current meter-meter, the combination with a movable measuring element, of means for exerting thereon a torque only when the current is out of phase with the pressure, a portion of said means comprising a movable field-winding capable of actuating said element, substantially as described.

9. In an alternating-current commutated meter-meter, the combination with a movable measuring element, of means for exerting thereon a torque only when the current is out of phase with the pressure, a part of said means comprising a movable winding for actuating said element, and a commutator for including the winding in circuit, substantially as described.

10. In an alternating-current meter-meter, the combination with a movable measuring element, of means for subjecting said element to the magnetic effect of two currents from a single circuit, means for maintaining one of said currents in quadrature with the pressure, a part of the first aforesaid means comprising a movable field-winding capable of actuating said element, substantially as described.

11. In an alternating-current commutated meter-meter, the combination with a movable measuring element, of means for subjecting said element to the magnetic effect of two currents from a single circuit, means for maintaining one of said currents in quadrature with the pressure, a part of the first aforesaid means comprising a movable field-winding capable of actuating said element, and a commutator for including said winding in circuit, substantially as described.

12. In a system of alternating-current distribution, the combination with an alternating-current generator, of series and shunt windings for producing magnetic fields, means for causing said fields to be substantially in phase with each other when the current and pressure are in quadrature, and for varying the phase between the fields as the phase between the current and pressure varies, one of said field-windings being movable, and a movable element actuated by the movable winding and subjected to the action of the fields, substantially as described.

13. In a system of alternating-current distribution, the combination with an alternating-current generator, of series and shunt windings for producing magnetic fields, means for causing said fields to be substantially in phase with each other when the current and pressure are in quadrature and for varying the phase between the fields as the phase between the current and pressure varies, one of said field-windings being movable, a movable element actuated by the movable winding and subjected to the action of the fields, and a commutator for including one of said windings in circuit, substantially as described.

14. In a system of alternating-current distribution, the combination with a source of alternating current, of series and shunt windings receiving current therefrom, one of the said windings being movable, a movable element subjected to the action of said movable winding, and means for maintaining the phase of the magnetism due to said shunt-winding substantially in quadrature with the pressure, substantially as described.

15. In a system of alternating-current distribution, the combination with a source of alternating current, of series and shunt windings in inductive relation with each other and receiving current therefrom, one of the said windings being movable, a movable element subjected to the action of said movable winding, and means for maintaining the phase of the magnetism due to said shunt-winding substantially in quadrature with the pressure, substantially as described.

16. In a system of alternating-current distribution, the combination with a source of alternating current, of series and shunt windings receiving current therefrom, the shunt-winding being movable, a movable element subjected to the action of said movable winding, means for maintaining the phase of the magnetism due to said shunt-winding substantially in quadrature with the pressure, and a commutator for including the shunt-winding in circuit, substantially as described.

17. In a system of alternating-current distribution, the combination with a source of alternating current, of series and shunt windings in inductive relation with each other and receiving current therefrom, the said shunt-winding being movable, a movable element subjected to the action of said movable winding, means for maintaining the phase of the magnetism due to said shunt-winding substantially in quadrature with the

pressure, and a commutator for including the short-winding in circuit, substantially as described.

18. In a system of alternating-current distribution, the combination with an alternating-current generator, of series and short windings receiving current therefrom, the short-winding being movable and constituting an armature, a measuring or indicating element actuated by the short-winding, and a phase-modifier or reactance, for maintaining the phase of the current due to the short-winding substantially in quadrature with the pressure, substantially as described.

19. In a system of alternating-current distribution, the combination with an alternating-current generator, of series and short windings receiving current therefrom, the short-winding being movable and constituting an armature, a measuring or indicating element actuated by the short-winding, inductance 8 in circuit with the armature, and adjusting means for modifying the action of the inductance to maintain the magnitude due to the short-winding in quadrature with the pressure, substantially as described.

20. In a system of alternating-current distribution, the combination with an alternating-current generator, of series and short windings receiving current therefrom, the short-winding being movable and constituting an armature, a measuring or indicating element actuated by the short-winding, inductance 8 in circuit with the armature, and a second inductance 9 to modify action of inductance 8 to maintain the phase of field due to the short-winding substantially in quadrature with the pressure, substantially as described.

21. In a system of alternating-current distribution, the combination with an alternating-current generator, of series and short windings receiving current therefrom, the short-winding being movable and constituting an armature, a measuring or indicating element actuated by the short-winding, inductance 8 in circuit with the armature, a second inductance 9 to modify action of inductance 8 to maintain the phase of field due to the short-winding substantially in quadrature with the pressure, and adjusting resistance 10 in circuit with the inductance 9, substantially as described.

22. In a system of alternating-current distribution, the combination with an alternating-current generator, of series and short windings receiving current therefrom, the short-winding being movable and constituting an armature, a measuring or indicating element actuated by the short-winding, inductance 8 in circuit with the armature, a second inductance 9 to modify action of inductance 8 to maintain the phase of field due to the short-winding substantially in quadrature with the pressure, an adjusting resistance 10 in circuit with the inductance 9, and a commutator for including the short-winding in circuit, substantially as described.

23. In an alternating-current meter, the combination with two field-windings, one of which is movable, of means for maintaining the field due to one of said windings in quadrature with the pressure, substantially as described.

698,666. ALTERNATING-CURRENT METER. THOMAS DUNNAN, Chicago, Ill., assigner to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 4, 1899. Renewed Dec. 10, 1901. Serial No. 94,664. (No model.)

Claim.—1. In an alternating-current meter, the combination with a reversible armature having a field-producing winding, of a second winding in cooperative relation therewith for producing a resultant magnetic field in quadrature with the pressure, substantially as described.

2. In an alternating-current meter the combination, with a reversible armature having a field-producing winding, of a second stationary winding in cooperative relation therewith for producing a resultant magnetic field in quadrature with the pressure, substantially as described.

3. In an alternating-current meter, the combination with a reversible armature having a field-producing winding, of a second winding in cooperative relation therewith for producing a resultant magnetic field in quadrature with the pressure, and a stationary field-winding associated with the armature, substantially as described.

4. In an alternating-current meter, the combination with a reversible armature having a field-producing winding, of a second stationary winding in cooperative relation therewith for producing a resultant magnetic field in quadrature with the pressure, and a stationary field-winding associated with the armature, substantially as described.

5. In an alternating-current meter, the combination with a pressure-winding, of a second field-winding, one of the said windings being reversible, means for independently supplying current to the said windings from an external source and a phase-modifying winding in cooperative relation with the pressure-winding, substantially as described.

6. In an alternating-current meter, the combination with a pressure-winding, of a second field-winding, one of the said windings being reversible, means for independently supplying current to the said windings from an external source and a phase-modifying winding in cooperative relation with the pressure-winding, substantially as described.

7. In an alternating-current meter, the combination with two field-windings, one of which is movable, of a phase-modifying winding in cooperative relation with one of said field-windings adapted to maintain the phase of the field due thereto substantially in quadrature with the pressure, substantially as described.

8. In an alternating-current meter, the combination with two field-windings, one of which is movable, of a phase-modifying winding in cooperative relation with one of said field-windings adapted to maintain the phase of the field due thereto substantially in quadrature with the pressure, and a commutator for supplying current to the movable winding, substantially as described.

9. In an alternating-current meter, the combination with pressure and ampere field-windings, one of which is movable, of a phase-modifying winding in cooperative relation with the pressure-winding and adapted to maintain the resultant magnetic field due to the latter winding substantially in quadrature with the pressure, substantially as described.

10. In an alternating-current meter, the combination with pressure and ampere field-windings, one of which is movable, of a phase-modifying winding in cooperative relation with the pressure-winding and adapted to maintain the resultant magnetic field due to the latter winding substantially in quadrature with the pressure, and a commutator for including the movable winding in circuit, substantially as described.

11. In an alternating-current meter, the combination with pressure and ampere field-windings, the pressure-winding being reversible, of a phase-modifying winding in cooperative relation with the pressure-winding for maintaining the phase of the resultant magnetic field due to the pressure-winding substantially in quadrature with the pressure, substantially as described.

12. In an alternating-current meter, the combination with pressure and ampere field-windings, the pressure-winding being reversible, of a phase-modifying winding in cooperative relation with the pressure-winding for maintaining the phase of the resultant magnetic field due to the pressure-winding substantially in quadrature with the pressure, and a commutator for including the pressure-winding in circuit, substantially as described.

13. In an alternating-current meter, the combination with pressure and ampere field-windings, the pressure-winding being reversible, of a phase-modifying winding in cooperative relation with the pressure-winding for maintaining the phase of the resultant magnetic field due to the pressure-winding substantially in quadrature with the pressure, and adjusting means for determining the current in the phase-modifying winding, substantially as described.

14. In an alternating-current meter, the combination with pressure and ampere field-windings, the pressure-winding being reversible, of a phase-modifying winding in cooperative relation with the pressure-winding for maintaining the phase of the resultant magnetic field due to the pressure-winding substantially in quadrature with the pressure, a commutator for including the pressure-winding in circuit, and adjusting means for determining the current in the phase-modifying winding, substantially as described.

15. In a system of distribution, the combination with an alternating-current generator, of pressure and ampere windings in circuit therewith, the pressure-winding being movable to have it curve by its motion to measure the wattless component of the current, of a phase-modifying winding supplied with current also from said source, and being in cooperative relation with the pressure-winding to produce and maintain a field substantially in quadrature with the pressure, and a commutator for including the pressure-winding in circuit, substantially as described.

16. In a system of distribution, the combination with an alternating-current generator, of pressure and ampere windings in circuit therewith, the pressure-winding being movable to have it curve by its motion to measure the wattless component of the current, of a phase-modifying winding supplied with current also from said source, and being in cooperative relation with the pressure-winding to produce and maintain a field substantially in quadrature with the pressure, and a commutator for including the pressure-winding in circuit, substantially as described.

17. In a system of distribution, the combination with an alternating-current generator, of pressure and ampere windings in circuit therewith, the pressure-winding being movable to have it curve by its motion to measure the wattless component of the current, of a phase-modifying winding supplied with current also from said source, and being in cooperative relation with the pressure-winding to produce and maintain a field substantially in quadrature with the pressure, and a commutator for including the pressure-winding in circuit, substantially as described.

18. In a system of distribution, the combination with an alternating-current generator, of pressure and ampere windings in circuit therewith, the pressure-winding being movable to have it curve by its motion to measure the wattless component of the current, of a phase-modifying winding supplied with current also from said source, and being in cooperative relation with the pressure-winding to produce and maintain a field substantially in quadrature with the pressure, and a commutator for including the pressure-winding in circuit, substantially as described.

substantially in quadrature with the pressure, substantially as described.

19. In a system of distribution, the combination with an alternating-current generator, of pressure and ampere windings in circuit therewith, the pressure-winding being movable to have it curve by its motion to measure the wattless component of the current, of a phase-modifying winding supplied with current also from said source, and being in cooperative relation with the pressure-winding to produce and maintain a field substantially in quadrature with the pressure, and a commutator for including the pressure-winding in circuit, substantially as described.

20. In a system of distribution, the combination with an alternating-current generator, of pressure and ampere windings in circuit therewith, the pressure-winding being movable to have it curve by its motion to measure the wattless component of the current, of a phase-modifying winding supplied with current also from said source, and being in cooperative relation with the pressure-winding to produce and maintain a field substantially in quadrature with the pressure, the phase-modifying winding and the ampere field-winding being at right angles to prevent mutual induction, substantially as described.

21. In a system of distribution, the combination with an alternating-current generator, of pressure and ampere windings in circuit therewith, the pressure-winding being movable to have it curve by its motion to measure the wattless component of the current, of a phase-modifying winding supplied with current also from said source and being in cooperative relation with the pressure-winding to produce and maintain a field substantially in quadrature with the pressure, and a commutator for including the pressure-winding in circuit, the phase-modifying winding and the ampere field-winding being at right angles to prevent mutual induction, substantially as described.

22. In a system of alternating-current distribution, the combination with an alternating-current generator, of a reversible pressure-winding for measuring by its motion the wattless component of alternating current, inductance in circuit with said winding, a phase-modifying winding in cooperative relation with the pressure-winding for maintaining the resultant field due thereto substantially in quadrature with the pressure, and an ampere-winding cooperating with the pressure-winding to produce a torque varying as the sine of the angle of lag between the current and pressure, substantially as described.

23. In a system of alternating-current distribution, the combination with an alternating-current generator, of a reversible pressure-winding for measuring by its motion the wattless component of alternating current, inductance in circuit with said winding, a phase-modifying winding in cooperative relation with the pressure-winding for maintaining the resultant field due thereto substantially in quadrature with the pressure, an ampere-winding cooperating with the pressure-winding to produce a torque varying as the sine of the angle of lag between the current and pressure, and adjusting means for determining the current in the phase-modifying winding, substantially as described.

24. In a system of alternating-current distribution, the combination with an alternating-current generator, of a reversible pressure-winding for measuring by its motion the wattless component of alternating current, inductance in circuit with said winding, a phase-modifying winding in cooperative relation with the pressure-winding for maintaining the resultant field due thereto substantially in quadrature with the pressure, an ampere-winding cooperating with the pressure-winding to produce a torque varying as the sine of the angle of lag between the current and pressure, and a commutator for including the pressure-winding in circuit, substantially as described.

25. In a system of alternating-current distribution, the combination with an alternating-current generator, of a reversible pressure-winding for measuring by its motion the wattless component of alternating current, inductance in circuit with said winding, a phase-modifying winding in cooperative relation with the pressure-winding for maintaining the resultant field due thereto substantially in quadrature with the pressure, an ampere-winding cooperating with the pressure-winding to produce a torque varying as the sine of the angle of lag between the current and pressure, adjusting means for determining the current in the phase-modifying winding, and a commutator for including the pressure-winding in circuit, substantially as described.

26. In a system of alternating-current distribution, the combination with an alternating-current generator, of a reversible pressure-winding for measuring by its motion the wattless component of alternating current, inductance in circuit with said winding, a phase-modifying winding in cooperative relation with the pressure-winding for maintaining the resultant field due thereto substantially in quadrature with the pressure, an ampere-winding cooperating with the pressure-winding to produce a torque varying as the sine of the angle of lag between the current and pressure, and adjusting means for determining the current in the phase-modifying winding, substantially as described.

698,667. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assigner to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 10, 1899. Renewed Jan. 6, 1902. Serial No. 94,664. (No model.)

Claim.—1. An electric meter provided with a rotary armature, a series field-coil mounted adjacent to the structure upon a rectangular magnetic core, and a pair of volt field-coils mounted upon the opposite side of the armature upon the pole of a U-shaped magnetic core, substantially as described.

2. An electric meter provided with the series coil A, volt-coils B, and armature C mounted on a spindle C' geared to a registering mechanism R, U-shaped laminated core D having volt-coils mounted on its pole, and a laminated core D' upon which the series coil A is mounted, said core being formed of laminations d' and d'' of which the laminations d' are of the shape and size of the space between the poles of the laminations d'' and can be struck without waste from the latter, substantially as described.

3. An electric meter, comprising a disk armature C mounted on a spindle C' connected with a registering mechanism, volt-coils B and auxiliary volt-coils B' mounted above the armature upon the downwardly-projecting pole of a U-shaped laminated core D, and series coil A mounted beneath the armature upon the upwardly-projecting laminated core D', substantially as described.

698,668. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assigner to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 10, 1899. Serial No. 726,498. (No model.)

Claim.—An electric meter comprising the disk armature C, laminated cores D and D' arranged symmetrically upon the opposite side of the armature with their poles in proximity thereto, volt field-coil B wound on one core, auxiliary volt-coil B' wound on the other core, and series field-coil A, mounted concentrically to the pole of the core, substantially as described.

698,669. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assigner to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 10, 1899. Serial No. 727,498. (No model.)

Claim.—1. An electric meter comprising a rotary armature, three-pole magnetic core D mounted on one side of the armature with its pole

terminating in proximity thereto, U-shaped magnetic core mounted on the opposite side of the armature with its poles terminating in proximity thereto, third core D' extending longitudinally between the poles of the U-shaped core, and coils mounted on said cores, substantially as described.

2. An electric motor comprising a rotary armature, series and volt coils for actuating said armature, a magnetic core upon which the volt-coil is mounted, an auxiliary core arranged with its poles in proximity to the main core, a coil mounted on said auxiliary core, and an auxiliary volt-coil mounted in inductive relation to the main volt-coil and connected in a closed circuit with the winding on the auxiliary core, substantially as described.

3. An electric motor comprising a rotary armature, series coil A and volt-coil B, U-shaped core D' upon which the volt-coil is mounted, core D'' extending between the poles of the core D', one or both of said cores being adjustably mounted, coil C mounted upon the core D', and coil B' mounted in inductive relation to the coil B and connected in a closed circuit with the coil C, substantially as described.

4. In a motor, the combination with the coils thereof for producing magnetic fields differing in phase, of a core for one of said coils formed in two portions having magnetic reluctance between the same, a coil B' on one of the core portions, and a coil B in circuit with said coil B' upon the other core portion, substantially as described.

5. In a motor, the combination with the coils thereof for producing magnetic fields differing in phase, of a core for one of said coils formed in two portions having magnetic reluctance between the same, one of said core portions containing the latter coil, a coil B' upon said core portion, and a coil B in circuit with said coil B' upon the other core portion, substantially as described.

6. In a motor, the combination with the coils thereof for producing magnetic fields differing in phase, of a core for one of said coils formed in two portions having magnetic reluctance between the same, one of said core portions containing the latter coil, a coil B' upon said core portion, a coil B in circuit with said coil B' upon the other core portion, and a phase-modifier V in circuit with the coils B', A, substantially as described.

7. In a motor, the combination with the coils thereof for producing magnetic fields differing in phase, of a core for one of said coils formed in two portions having magnetic reluctance between the same, one of said core portions containing the latter coil, a coil B' upon said core portion, a coil B in circuit with said coil B' upon the other core portion, and a phase-modifier V in circuit with the coils B', A, substantially as described.

8. In a motor, the combination with the coils thereof for producing magnetic fields differing in phase, of a core for one of said coils formed in two portions having magnetic reluctance between the same, one of said core portions containing the latter coil, a coil B' upon said core portion, a winding B in circuit with said coil B' upon the other core portion, and a phase-modifying resistance V in circuit with the coils B', A, substantially as described.

9. A motor provided with two windings for producing magnetic fields differing in phase, one of said windings being divided into two field-coils, of a secondary coil in inductive relation with one of the field-coils, which field-coil then constitutes a primary inducing winding, the second field-coil being included in a closed circuit with, and supplied by, current from said secondary coil, substantially as described.

698,670. ALTERNATING-CURRENT METER. THOMAS DUNBAR, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 15, 1906. Renewed Dec. 16, 1907. Serial No. 58,697. (No model.)

Claim.—1. In an alternating-current meter, the combination with a measuring element, of electromagnetic torque-producing means adapted in cooperation with said measuring element, to measure the "true" watts in an alternating-current circuit, a second electromagnetic torque-producing means adapted, in cooperation with said measuring element, to measure the wattless component in an alternating-current circuit, and means for bringing a torque-producing means into and out of operative association with the measuring element, substantially as described.

2. In an alternating-current meter, the combination with a measuring element, of electromagnetic torque-producing means adapted in cooperation with said measuring element, to measure the "true" watts in an alternating-current circuit, a second electromagnetic torque-producing means adapted, in cooperation with said measuring element, to measure the wattless component in an alternating-current circuit, and means for bringing each torque-producing means into and out of operative association with the measuring element, substantially as described.

3. In a system of alternating-current distribution, the combination with an alternating-current generator, of a movable element and electromagnetic means receiving current from said generator for exerting two torques upon the movable element, one capable of causing movement of said element proportional to the "true" watts, and the other, movement of said element proportional to the magnetizing component of the alternating current, and means whereby said element may be subjected to either one only of said torques, substantially as described.

4. In a system of alternating-current distribution, the combination with an alternating-current generator, of a movable element, electromagnetic means receiving current from said generator for exerting two torques upon said element respectively proportional to the "true" watts and the magnetizing component, and means whereby said element may be subjected to one only of said torques, substantially as described.

5. In a system of alternating-current distribution, the combination with an alternating-current generator, of a movable element, electromagnetic means receiving current from said generator for exerting two torques upon said element respectively proportional to the "true" watts and the magnetizing component, and means whereby said element may be subjected to either of said torques, substantially as described.

6. In an alternating-current meter, the combination with means for producing two pressure-fields substantially in quadrature with each other, of means for producing a third field by, and varying in phase with, the current, and a movable measuring element, the latter field in cooperation with one of the pressure-fields serving to actuate said measuring element to determine the "true" watts and in cooperation with the other field to move said element to determine the magnetizing component, and means whereby said element may be subjected to the action of either one only of said torques, substantially as described.

7. In an alternating-current meter, the combination with means for producing two pressure-fields substantially in quadrature with each other, of means for producing a third field by, and varying in phase with the current, a movable measuring element, and means whereby said measuring element may be subjected to the action of the current-field and one pressure-field only, substantially as described.

8. In an alternating-current meter, the combination with a measuring element, of pressure and current field-windings for producing torques

upon the measuring element proportional to the "true" watts and to the magnetizing component, and means for limiting the measuring element to the action of one of the torques, substantially as described.

9. In an alternating-current meter, the combination with a measuring element, of pressure and current field-windings for producing torques upon the measuring element proportional to the "true" watts and to the magnetizing component, and means for permitting said element to be subjected to either torque alone, substantially as described.

10. In an alternating-current meter, the combination with a measuring element, of pressure and current field-windings for producing torques upon the measuring element proportional to the "true" watts and to the magnetizing component, and switching means adapted to control the continuity of circuit connections for limiting the measuring element to the action of one of the torques, substantially as described.

11. In an alternating-current meter, the combination with a measuring element, of two sets of windings each comprising a current and pressure winding for producing torques upon the measuring element proportional to the "true" watts and to the magnetizing component, and switching means adapted to control the continuity of circuit connections for limiting the measuring element to the action of one of the torques, substantially as described.

12. In an alternating-current meter, the combination with a measuring element, of means for producing torques proportional to the true watts and to the magnetizing component, and means for limiting the measuring element to the action of one of said torques, substantially as described.

698,671. ALTERNATING-CURRENT METER. THOMAS DUNBAR, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 15, 1906. Renewed Dec. 16, 1907. Serial No. 58,698. (No model.)

Claim.—1. In an alternating-current meter, the combination with a measuring element, of pressure-windings, a current-coil common to both pressure-windings, said windings serving to produce torques upon the measuring element proportional to the "true" watts and to the magnetizing component, and means for limiting the measuring element to the action of one of the torques, substantially as described.

2. In an alternating-current meter, the combination with a measuring element, of pressure-windings, a current-coil common to both pressure-windings, said windings serving to produce torques upon the measuring element proportional to the "true" watts and to the magnetizing component, and means for permitting said element to be subjected to either torque alone, substantially as described.

3. In an alternating-current meter, the combination with a measuring element, of pressure-windings, a current-coil common to said pressure-windings, said windings serving to cause torques upon the measuring element proportional to the "true" watts and to the magnetizing component, and switching mechanism for rendering a pressure-winding inoperative, substantially as described.

4. In an alternating-current meter, the combination with a measuring element, of pressure-windings, a current-coil common to said pressure-windings, said windings serving to cause torques upon the measuring element proportional to the "true" watts and to the magnetizing component

and switching mechanism for rendering either pressure-winding inoperative, substantially as described.

5. In an alternating-current meter, the combination with a measuring element, of pressure-windings, a current-coil common to said pressure-windings, said windings serving to cause torques upon the measuring element proportional to the "true" watts and to the magnetizing component, and switching mechanism adapted to open a pressure-winding circuit, substantially as described.

698,672. ALTERNATING-CURRENT METER. THOMAS DUNBAR, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 15, 1906. Renewed Jan. 2, 1908. Serial No. 58,699. (No model.)

Claim.—1. In an alternating-current meter, the combination with a measuring element, of a current-winding, a pressure-winding, a means adapted to cooperate with the pressure-winding to produce a resultant magnetic field which with the current-field serves to exert a torque upon said measuring element proportional to the "true" watts, and a second means adapted to cooperate with the same pressure-winding to produce a resultant field which with the current-field serves to exert torque upon said measuring element proportional to the magnetizing component, substantially as described.

2. In an alternating-current meter, the combination with a measuring element, of a current-winding, a pressure-winding, means adapted to cooperate with the pressure-winding to produce a resultant magnetic field which with the current-field serves to move the measuring element proportionally to the "true" watts, a second means adapted to cooperate with the same pressure-winding to produce a resultant magnetic field which with the current-field serves to move said measuring element proportionally to the wattless component, and means for associating either of the abovesaid means with said pressure-winding independently of the other, substantially as described.

3. In an alternating-current meter, the combination with a measuring element, of means for exerting torques proportional to the "true" watts, and means for exerting torque upon said element proportional to the magnetizing component, a single pressure-winding being common to, and comprising a portion of, both of said means, substantially as described.

4. In an alternating-current meter, the combination with a measuring element, of means for moving the same proportionally to the "true" watts, second means for moving the measuring element proportional to the wattless component, a single pressure-winding being common to both of said means, and means for associating either of the abovesaid means with said pressure-winding independently of the other, substantially as described.

5. In an alternating-current meter, the combination with a movable measuring element, of a pressure field-winding, a phase-modifying means for bringing the field of the said pressure-winding in phase with the pressure, and a second phase-modifying means for bringing the field thereof in quadrature with the pressure, substantially as described.

6. In an alternating-current meter, the combination with a movable measuring element, of a pressure field-winding, a phase-modifying means for bringing the field of the said pressure-winding in phase with the pressure, a second phase-modifying means for bringing the field of said pressure-winding in quadrature with the pressure, and switching apparatus for bringing either of said means in cooperative relation with the pressure-winding independently of the other, substantially as described.

7. In an alternating-current meter, the combination with a movable measuring element, of a pressure field-winding, a phase-modifying means for bringing the field of the said pressure-winding in phase with the pressure, a second phase-modifying means for bringing the field of said pressure-winding in quadrature with the pressure, and switching apparatus for bringing either of said means in cooperative relation with the pressure-winding independently of the other, substantially as described.

sure-winding in quadrature with the pressure, a current-winding for producing a field varying in phase with the current, and switching apparatus for bringing either of the said means in cooperative relation with the pressure-winding independently of the other, substantially as described.

8. In an alternating-current meter, the combination with a measuring element, of a current field-winding for producing a field varying in phase with the current, a pressure field-winding, an auxiliary circuit, resistance, and switching apparatus for including resistance in circuit with the pressure-winding and at the same time including resistance in said auxiliary circuit, or for including resistance in circuit with the pressure-winding and at the same time including resistance in the auxiliary circuit, substantially as described.

9. In an alternating-current meter, the combination with a movable measuring element, of a current-winding, a pressure-winding, phase-modifying means adapted in cooperation with said current and pressure windings to exert a torque upon the measuring element proportional to the "true" watts, second phase-modifying means adapted in cooperation with said current and pressure winding to exert a torque upon the measuring element proportional to the magnetizing component, and switching apparatus for associating either of said phase-modifying means with said pressure-winding, substantially as described.

10. In an alternating-current meter, the combination with a movable element, of a field-winding, two magnetic phase-modifying means of different electrical character for modifying the phase of magnetism due to said field-winding, and means whereby one phase-modifying means may be associated with said field-winding independently of the other, substantially as described.

11. In an alternating-current meter, the combination with a movable element, of a field-winding, two magnetic phase-modifying means of different electrical character for modifying the phase of magnetism due to said field-winding, and means for independently associating each phase-modifying means with, and disconnecting it from, the field-winding, substantially as described.

698,678. ELECTRIC METER. THOMAS DUNBAR, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 27, 1906. Serial No. 736,966. (No model.)

Claim.—1. In a commutated motor-meter, a series field-coil, a short-wound armature, a magnetizing-coil that is magnetically coaxial with said armature, and means for integrating the revolutions of said armature.

2. In a motor-meter of the class described, a series field coil or coils, a movable armature, a magnetizing-coil that is magnetically coaxial with said armature and at right angles to the magnetic axis of said series field coil or coils, and means for integrating the revolutions of said armature.

3. In a motor-meter of the class described, a series field-coil, a short-wound reversible armature, a commutator for said armature, a magnetizing coil or coils having the same magnetic axis as said armature, the magnetic axis of both the armature and magnetizing coil or coils at an angle to the magnetic axis of said series field-coil, a magneto-electric damping device, and means for integrating the revolutions of said armature.

4. In an energy meter of the class described, a series field-coil, a reversible armature, means for conducting current into said armature from the source of pressure, a non-inductive resistance in series with the armature, a magnetizing-coil receiving current from the same source of pressure as said armature, the current of the magnetizing-coil having a different time-

period from the current traversing said armature, and means for lagging the current traversing the magnetizing-coil.

5. In a motor for measuring alternating currents, a series field-coil, a short-wound armature, a non-inductive resistance in series with said armature, a magnetizing-coil in cooperative relation with said armature, an impedance-coil in series with said magnetizing-coil, the magnetic axis of the series field and magnetizing coils being at right angles, a contact device for conducting current to the armature, a magneto-electric damping device, and an integrating mechanism responding to the revolutions of the armature.

6. The combination with a motor for alternating currents of a series field-coil, a short-wound armature having its magnetic or polar axis at an angle to the polar axis of said series field-coil, a magnetizing-coil that is magnetically coaxial with said armature, and means for lagging the current traversing said magnetizing-coil.

7. In a commutated motor-meter, the combination with a commutated short-wound armature, of a field-winding, and a phase-modifying winding in inductive relation with said armature, substantially as described.

8. In a commutated motor-meter, the combination with a commutated short-wound armature, of a field-winding, and a phase-modifying winding in inductive relation with said armature, and connected in parallel therewith in the work-circuit, substantially as described.

698,674. ALTERNATING-CURRENT METER. THOMAS DUNBAR, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 24, 1906. Serial No. 736,178. (No model.)

Claim.—1. In a three-phase system of alternating-current distribution, the combination with a current-winding supplied with current from one of the transmission-conductors, of a second current field-winding supplied with current from the remaining transmission-conductors, a pressure-winding associated with each of said current-windings, a measuring element subjected to the action of the fields due to the said windings, and means associated with the circuits including the pressure-windings for maintaining the fields due to the pressure-windings substantially in quadrature with the pressure upon the circuits including the same, substantially as described.

2. In a polyphase system of electrical distribution, the combination with a source of polyphase alternating current, of transmission-conductors for conveying polyphase currents, a current-winding producing a field proportional to the current in one transmission-conductor, a pressure-winding producing a field proportional to the resultant of two pressures impressed on said transmission-conductors, the said two windings serving conjointly to exert torque upon an armature, a second current-winding producing a field proportional to the resultant of two currents of displaced phase traversing said transmission-conductors, a second pressure-winding producing a field proportional to the pressure of one of the circuits impressed on said transmission-conductors, the last two abovesaid coacting windings serving together to exert torque upon an armature, and a measuring element subject to the action of the said torque, substantially as described.

3. In a polyphase system of electrical distribution, the combination with a source of polyphase alternating current, of transmission-conductors for conveying polyphase currents, a current-winding producing a field proportional to the current in one transmission-conductor, a pressure-wind-

ing producing a field proportional to the resultant of two distinct pressures impressed on said transmission-conductors, a second current-winding producing a field proportional to the resultant of two out-of-phase currents traversing two separate transmission-conductors, a second pressure-winding producing a field proportional to the pressure of a circuit impressed on said transmission-conductors, a measuring element inductively associated with said field-windings to measure the power of the system, and means for maintaining the fields due to the pressure-windings in quadrature with the pressures impressed on their respective circuits, substantially as described.

4. In a system of alternating-electric-current distribution, the combination with a source of three-phase alternating current in circuit with the three transmission-mains of the system, of a current field-winding receiving current from one of the mains, a compensator 19 between the remaining two mains, a conductor 18 receiving current from said compensator and the first abovesaid transmission-main, a second field-winding receiving its current from said conductor, and an armature subject to said fields, the said fields by their conjoint action serving to exert torque upon said armature, substantially as described.

5. In a system of alternating-electric-current distribution, the combination with a source of three-phase alternating current in circuit with the three transmission-mains of the system, of a current field-winding receiving current from one of the mains, a compensator 19 between the remaining two mains, a conductor 18 receiving current from said compensator and the first abovesaid transmission-main, a second field-winding receiving its current from said conductor, a motive element inductively acted upon by the fields due to the field-windings, and means for adjusting the phase relation of said fields, substantially as described.

6. In a system of alternating-electric-current distribution, the combination with a source of three-phase alternating current in circuit with the three transmission-mains of the system, of a current field-winding receiving current from one of said mains, a compensator between the remaining two mains, a conductor extending between an intermediate portion of said compensator and the first abovesaid transmission-main, a second field-winding receiving its current from said conductor, and a motive element subjected to the action of said fields, substantially as described.

7. In a system of alternating-electric-current distribution, the combination with a source of three-phase alternating current in circuit with the three transmission-mains of the system, of a current field-winding receiving current from one of said mains, a compensator between the remaining two mains, a conductor extending between an intermediate portion of said compensator and the first abovesaid transmission-main, a second field-winding receiving its current from said conductor, a motive element inductively acted upon by the fields due to the field-windings, and means for adjusting the phase relation of the fields, substantially as described.

8. In a system of alternating-current distribution, the combination with two conductors, of means for supplying the same with alternating currents differing in phase, a current field-winding supplied with current from each of said mains and serving to produce a field which is proportional to the resultant of the currents in said mains, a pressure field-winding serving to create a second field proportional to the pressure between said conductors, a movable element inductively acted upon by the fields due to the field-windings, and means for adjusting the phase relation of the fields, substantially as described.

9. In a system of alternating-current distribution, the combination with a source of three-phase current in circuit with the mains of the system, of a current field-winding supplied with out-of-phase currents from two of the mains and serving to produce a field proportional to the resultant of the currents in the latter mains, a pressure field-winding serving to create a field proportional to the pressure between the latter two windings, a movable element inductively acted upon by the fields due to the field-windings, and means for adjusting the phase relation of the fields, substantially as described.

10. In a system of current distribution, the combination with a source of three-phase current in circuit with the three transmission-mains of the system, of a current field-winding receiving current from one of the mains of the system, a pressure field-winding adapted to create a pressure field proportional to the resultant of the pressures between the latter main and each of the other mains of the system, a second current-winding receiving current from each of the remaining mains of the system and serving to create a field proportional to the resultant of the currents in the latter mains, a second pressure-winding for creating a field proportional to the pressure between the latter main, and a measuring element subjected to the action of said fields to measure the power of the system, substantially as described.

11. In a system of electrical distribution, the combination with a source of three-phase current in circuit with the three transmission-mains of the system, of a current field-winding receiving current from one of the mains of the system, a pressure field-winding adapted to create a pressure field proportional to the resultant of the pressures between the latter

main and each of the other mains of the system, a second current-winding receiving current from each of the remaining mains of the system and serving to create a field proportional to the resultant of the currents in the latter mains, a second pressure-winding for creating a field proportional to the pressure between the latter main, an armature associated with the first two field-windings, and a second armature subjected to the second two field-windings to measure the power of the system, substantially as described.

12. In a system of electrical distribution, the combination with a source of three-phase current in circuit with the three transmission-mains of the system, of a current field-winding receiving current from one of the mains of the system, a pressure field-winding adapted to create a pressure field proportional to the resultant of the pressures between the latter main and each of the other mains of the system, a second current-winding receiving current from each of the remaining mains of the system and serving to create a field proportional to the resultant of the currents in the latter mains, a second pressure-winding for creating a field proportional to the pressure between the latter main, an armature associated with the first two field-windings, a second armature subjected to the second two field-windings to measure the power of the system, and a measuring element, said armature cooperating with the measuring element to measure the power in the system, substantially as described.

13. In a system of electrical distribution, the combination with a source of three-phase current in circuit with the three transmission-mains of the system, of a current field-winding receiving current from one of the mains of the system, a pressure field-winding adapted to create a pressure field proportional to the resultant of the pressures between the latter main and each of the other mains of the system, a second current-winding receiving current from each of the remaining mains of the system and serving to create a field proportional to the resultant of the currents in the latter mains, a second pressure-winding for creating a field proportional to the pressure between the latter main, a measuring element inductively acted upon by said fields, and means for adjusting the phase relation of the fields, substantially as described.

14. In a system of electrical distribution, the combination with a source of three-phase current in circuit with the three transmission-mains of the system, of a current field-winding receiving current from one of the mains of the system, a pressure field-winding adapted to create a pressure field proportional to the resultant of the pressures between the latter main and each of the other mains of the system, a second current-winding receiving current from each of the remaining mains of the system and serving to create a field proportional to the resultant of the currents in the latter mains, a second pressure-winding for creating a field proportional to the pressure between the latter main, an armature being inductively associated with the said field-windings, a second armature subjected to the second two field-windings to measure the power of the system, a measuring element, said armature being inductively associated with said field-windings to measure the power of the system, and means for adjusting the phase relation of the fields, substantially as described.

15. In a polyphase system of electrical distribution, the combination with a source of polyphase alternating current, of a current-winding producing a field proportional to the current in one transmission-conductor, a pressure-winding producing a field proportional to and displaced substantially ninety degrees from the resultant of two pressures of the system, said windings serving conjointly to exert torque upon an armature, a second current-winding producing a field proportional to the resultant of two currents of the system, a second pressure-winding producing a field displaced substantially ninety degrees from the pressure of one circuit of the system, said pressure-winding receiving its current from the two mains of the system including the coils of the last abovesaid current-winding, and a measuring element subject to the action of said fields to measure the power of the system, substantially as described.

16. In a polyphase system of electrical distribution, the combination with a source of polyphase current, of a current-winding producing a field proportional to the current in one transmission-conductor, a pressure-winding producing a field proportional to the resultant of two pressures of the system cooperatively associated with said current-winding, an armature subject to the torque created by the conjoint action of said fields, a second current-winding producing an effective field proportional to the resultant of two currents of the system, a second pressure-winding producing a field proportional to the pressure of one circuit of the system, the said second pressure-winding receiving its current from the mains including coils of the last abovesaid current-winding, and a second armature subject to the torque produced by the conjoint action of said latter fields, substantially as described.

17. In a three-phase system of electrical distribution, the combination with a source of three-phase alternating current, of a current-winding producing a field proportional to the current in one transmission-conductor, a pressure-winding producing a field proportional to the resultant of two pressures of the system cooperatively associated with said current-

winding, a second current-winding producing a field proportional to the resultant of two currents of the system, a second pressure-winding producing a field proportional to the pressure between the two remaining transmission-conductors of the system associated with said second current-winding, the said second pressure-winding receiving its current from the main including the coils of the second current-winding and a measuring element subject to the torque produced by the first ohmic out of field and also to the torque of the last ohmic out of field, substantially as described.

18. In a three-phase system of electrical distribution, the combination with a source of three-phase current, of a motor-motor having two armatures, a current field-winding supplied with current from one of the transmission-conductors associated with one of said armatures, a second current field-winding supplied with current from the remaining transmission-conductors associated with the second armature, and a pressure-winding associated with each of said current-windings, the pressure-winding associated with the last ohmic out of field-winding receiving its current from the two transmission-conductors of the system including the coils of the said second current field-winding, substantially as described.

19. In a polyphase system of alternating-current distribution, the combination with a source of three-phase current in circuit with the main of the system, of a compensator connected between two of the mains, a pressure-winding cooperatively associated with said current-winding receiving its current from a conductor extending between an intermediate portion of said compensator and a transmission-main, means for maintaining the field due to the pressure-winding substantially in quadrature with the pressure impressed on its circuit, and a measuring element subject to the action of said field, substantially as described.

20. In a system of alternating-current distribution, the combination with a source of three-phase current in circuit with the main of the system, of a current field-winding supplied with out-of-phase currents from two of the mains and serving to produce a field proportional to the resultant of the currents in the latter mains, a pressure field-winding serving to create a field proportional to the pressure between the latter two windings, a movable element subject to the conjoint action of said windings, and means for maintaining the field due to the pressure-winding in quadrature with the pressure impressed on the terminals of the pressure-circuit, substantially as described.

21. In a system of polyphase-alternating-current distribution, the combination with a source of current connected to transmission-mains, of a current field-winding receiving current from one main of said system, a pressure-winding receiving its current from said main and associated mains, thereby to create a field proportional to the resultant of two pressures of the system, and an armature subject to the conjoint action of said field, substantially as described.

22. In a polyphase system of electrical distribution, the combination with a source of polyphase current, of a current-winding producing a field proportional to the current in one transmission-conductor, a pressure-winding producing a field proportional to the resultant of two pressures of the system cooperatively associated with said current-winding, an armature subject to the torque created by the conjoint action of said field, a second current-winding producing an effective field proportional to the resultant of two currents of the system, a second pressure-winding producing a field proportional to the pressure of one circuit of the system, the said second pressure-winding receiving its current from the transmission-conductors including the coils of the second ohmic out of field-winding, a second armature subject to the torque produced by the conjoint action of said field, and a single measuring element actuated by both of said armatures, substantially as described.

23. In a system of polyphase-alternating-current distribution, the combination with a source of current connected to transmission-mains, of a current field-winding receiving current from one main of said system, a pressure-winding receiving its current from said main and associated mains, thereby to create a field proportional to the resultant of two pressures of the system, an armature subject to the conjoint action of said field, and means for maintaining the field due to the pressure-winding in quadrature with the pressure impressed on the terminals of the pressure-circuit, substantially as described.

24. In an induction-motor for three-phase circuits, a main current-winding comprising a plurality of sections suitably connected to the three-phase mains, a shunt-winding connected across points, the potential between which is in phase with the resultant of the currents in the sections of the main current-winding on non-inductive load, and means for causing the magnetic field due to the shunt-winding to be displaced by substantially ninety degrees from electrostatic force impressed upon the shunt-circuit.

25. In an induction-motor for three-phase circuits, a main current-winding comprising a plurality of coils each connected in circuit with one of the three-phase mains, a shunt-winding connected between two of the mains, and means for causing the field due to the shunt-winding to be displaced by substantially ninety degrees from the electrostatic force impressed upon the shunt-circuit.

placed by substantially ninety degrees from the electrostatic force impressed upon the shunt-circuit.

26. In an induction-motor for three-phase circuits, a main current-winding comprising two coils each connected in circuit with one of the three-phase mains, a shunt-winding connected between the mains in which the series coils are included, and means for causing the field due to the shunt-winding to be displaced by substantially ninety degrees from the electrostatic force impressed on the shunt-circuit.

698,675. ELECTRIC METER. THOMAS DUNN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Nov. 27, 1898. Serial No. 734,267. (No model.)

Claim.—1. In an alternating-current meter a series coil, a shunt-wound armature, a phase-changing coil in series with said armature, and extraneous means associated with said phase-changing coil for bringing the field due to said armature in phase with the circuit-pressure, substantially as described.

2. In an alternating-current meter a series coil, a shunt-wound armature representing the electrostatic force, a phase-changing coil in circuit with said shunt-wound element and extraneous means associated with said phase-changing coil for varying the phase relation of the circuit including said phase-changing coil and said shunt-wound armature, and bringing the field due to the shunt-wound element in phase with the circuit-pressure, substantially as described.

3. In an alternating-current meter, a series coil, a shunt-wound armature representing the pressure-receiving current from the circuit-mains, a non-inductive resistance in series with said armature, a phase-changing coil in series with the said armature and the non-inductive resistance, an inducing-coil in cooperative relation with the phase-changing coil, and means associated with the circuit including the phase-changing coil and the armature for bringing the field due to the armature in phase with the circuit-pressure, substantially as described.

4. In an alternating-current meter a series coil, a shunt-wound armature; means connected with the circuit-mains for conducting current through the windings of said armature; a phase-changing coil in series with said armature; a non-inductive resistance in series with the armature and phase-changing coil; and an inducing-coil in inductive relation to the phase-changing coil also connected with the circuit-mains; and a variable resistance in series with said inducing-coil.

5. In an alternating-current meter a series coil, a shunt-wound armature metallically connected to and receiving current from the circuit-mains; a commutator for said armature; a non-inductive resistance in series with said armature; a phase-changing coil also receiving current from the circuit-mains in cooperative relation with the shunt-wound armature and non-inductive resistance serving to bring the field due to the armature in phase with the pressure; and means for retarding the revolutions of said armature.

6. In an alternate-current electric meter a series coil, a shunt-armature winding, the magnetism of which varies as the pressure in volts; said armature receiving its current conductively from the circuit-mains; a resistance in series with said shunt or armature winding; a phase-changing coil in cooperative relation with the shunt or armature winding; an inducing-coil also receiving current conductively from the said circuit-mains in inductive relation with the phase-changing coil; a variable resistance in series with the inducing-coil; and an integrating mechanism.

7. In an alternating-current electric meter a series coil, a revolvable shunt-wound armature, a transformer comprising a primary or inducing coil, a secondary or phase-changing coil, the primary connected to the source of pressure and the secondary connected in series with the shunt-wound armature and a variable resistance in series with the primary or

inducing coil, and serving to cause the magnetism due to the armature in phase with the pressure, said armature also receiving current conductively from the source of pressure substantially as described.

8. In an alternating-current meter, the combination with a shunt-wound armature, said armature being adapted for connection with circuit-mains, of an electromagnetic phase-changing device associated extraneously with the armature-circuit, for bringing the effective magnetism due to said armature-circuit in phase with the circuit-pressure, substantially as described.

698,676. ELECTRIC METER. THOMAS DUNN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Jan. 2, 1899. Renewed Jan. 2, 1902. Serial No. 84,457. (No model.)

Claim.—1. In a meter, the combination with a current-conductor having parallel paths and adapted for inclusion in series with a main conductor, of an armature adapted for interposition between the sides of the circuit, the said armature being disposed between the said parallel paths, the armature being provided with two adjacent windings free of a current-field portion between them and so related that current will pass through the same in opposite directions, substantially as described.

2. In a meter, the combination with a closed conductor 2, of terminal points 12, 12, securing the conductor in place and connected with opposite sides thereof, whereby parallel paths are afforded for current passing through the conductor, and an armature induced by the conductor, the armature having two adjacent windings free of a current-field portion between them and so relatively arranged that current will pass through the same in opposite directions, said windings being adapted for inclusion in bridge between the sides of the distributing-circuit, substantially as described.

3. In a meter, the combination with a current-conductor having parallel paths and adapted for inclusion in series with a main conductor, of an armature adapted for interposition between the sides of the circuit, said armature being disposed between the said parallel conductors, the armature being provided with two adjacent windings free of a current-field portion between them, a commutator common to the said windings, and means for effecting connection between the said windings and the sides of the distributing-circuit, substantially as described.

4. In a meter, the combination with a current-conductor having parallel paths and adapted for inclusion in series with a main conductor, of an armature adapted for interposition between the sides of the circuit, said armature being disposed between the said parallel conductors, the armature being provided with two adjacent windings free of a current-field portion between them, a commutator common to the said windings, and commutator brushes engaging the commutator for including the said windings between the sides of the distributing-circuit, substantially as described.

5. In a meter, the combination with a current-conductor having parallel paths and adapted for inclusion in series with a main conductor, of an armature adapted for interposition between the sides of the circuit, said armature being disposed between the said parallel conductors, the armature being provided with two adjacent windings free of a current-field portion between them, a collector common to the said windings, and

means for effecting connection between the said windings and the sides of the distributing-circuit, the windings of the armature being so relatively disposed that current will flow through the same in opposite directions, substantially as described.

6. In a meter, the combination with a current-conductor having parallel paths and adapted for inclusion in series with a main conductor, of an armature adapted for interposition between the sides of the circuit, said armature being provided with two adjacent windings free of a current-field portion between them, a commutator common to the said windings, and commutator brushes engaging the commutator for including the said windings between the sides of the distributing-circuit, the windings of the armature being so relatively disposed that current will flow through the same in opposite directions, substantially as described.

7. In a meter, the combination with the rotatable retarding element thereof, of a permanent magnet cooperating therewith to check the speed of rotation of the movable member of the meter, and a portion of magnetic material in movable contact with the pole of said magnet for short-circuiting lines of force threading the magnet away from the retarding element and confining them to the closed magnetic circuit including the permanent magnet, substantially as described.

8. In a meter, the combination with the rotatable retarding element thereof, of two permanent magnets for retarding the rotation of the movable member of the meter included in a closed magnetic circuit to short-circuit lines of force threading the magnets, to reduce the number of lines of force threading the rotatable element, substantially as described.

9. In a meter, the combination with the rotatable retarding element thereof, of two permanent magnets therefor, having direct contact with each other to short-circuit lines of force threading the magnets to reduce the number of lines of force threading the disk, substantially as described.

10. In a meter, the combination with the rotatable retarding element thereof, of two permanent magnets therefor, having direct contact with each other to short-circuit lines of force threading the magnets to reduce the number of lines of force, and means for adjusting the said magnets with relation to the said rotatable retarding element, without removing the magnets from contact with each other, substantially as described.

11. In a meter, the combination with the rotatable retarding element thereof, of two permanent magnets therefor, having direct contact with each other to short-circuit lines of force threading the magnets to reduce the number of lines of force threading the disk, and a support for the magnets provided with parallel guiding-slots and clamping-curves passing through the guiding-slots for securing the magnets in place, whereby the magnets may be adjusted with relation to the rotatable retarding element without being removed from contact with each other, substantially as described.

12. In a meter, the combination with a rotatable armature adapted to be supplied with current through its coils from a distributing-circuit, of an adjustable magnet cooperating therewith for correcting the movement of the armature, substantially as described.

13. In a meter, the combination with a rotatable armature adapted to be supplied with current through its coils from a distributing-circuit, of magnetic means cooperating therewith to correct the movement thereof, the said magnetic means being adjustable, whereby a pole of either sign may be presented to the armature, substantially as described.

14. In an electric meter, the combination with a rotatable armature having a winding adapted to receive current from a distributing-circuit, of a rotatable-adjustable magnetic device for correcting the movement of the armature, substantially as described.

15. In a meter, the combination with an armature provided with two windings or sets of coils, of a pair of magnets each cooperating with an armature-winding, whereby error in the movement of the armature may be corrected, substantially as described.

16. In a meter, the combination with an armature provided with windings through which current is adapted to flow in opposite directions, of a pair of magnets presenting unlike poles to the said windings, substantially as described.

17. In a meter, the combination with an armature provided with windings, through which current is adapted to flow in opposite directions, of a pair of magnets presenting unlike poles to the said windings, the said windings being rotatably mounted, whereby the poles presented to the armature-windings may be reversed, substantially as described.

18. In a meter, the combination with the rotatable armature thereof, adapted to receive current from a distributing-circuit, of an electromagnetic device having a winding included in circuit with the said armature, the said magnet serving to create poles of unlike sign, the said magnet serving to correct error in the movement of the armature, substantially as described.

19. In a meter, the combination with the rotatable armature thereof, adapted to receive current from a distributing-circuit, of an electromagnetic

notio device having a winding included in circuit with the said armature, the said magnet serving to create poles of unlike sign, the said magnet serving to correct error in the movement of the armature, the magnet being rotatable, whereby a pole of either sign may be presented to the armature, substantially as described.

20. In a meter, the combination with a rotatable armature adapted to be supplied with current through its coils from a distribution-circuit, of a magnetic device cooperating therewith for correcting the movement of the armature, and means for reversing the polarity of the magnet as it is presented to the armature, substantially as described.

21. In a meter, the combination with its rotatable retarding element thereof, of a permanent magnet cooperating therewith in circuit the speed of rotation of the movable member of the meter, and a portion of magnetic material opened in portions of both poles of the permanent magnet and conveying lines of force from one pole of said magnet to the other, whereby lines of force threading the magnet are short-circuited away from the retarding element and confined to the magnetic circuit comprising the magnet and the said portion of magnetic material, substantially as described.

698,677. ELECTRIC METER. THOMAS DUGAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Jan. 2, 1900. Renewed Dec. 15, 1901. Serial No. 95,000. (No model.)

Claim.—1. In a wattmeter, the combination with an S-shaped field-conductor, of an armature having windings induced by the convolutions of said conductor, and means for connecting said windings in bridge between the sides of the circuit in which the current is being measured, substantially as described.

2. In a meter, the combination with an S-shaped field-conductor, of an armature having windings induced by the convolutions of said conductor, the windings of the said armature being connected to have current flow through the same in opposite directions, substantially as described.

3. In a meter, the combination with an S-shaped field-conductor, of an armature having windings induced by the convolutions of said conductor, and a collecting device common to the windings of the armature, substantially as described.

4. In a meter, the combination with an S-shaped field-conductor, of an armature having windings induced by the convolutions of said conductor, and a commutator common to the windings of the armature, substantially as described.

5. In a meter, the combination with an S-shaped field-conductor, of an armature having windings induced by the convolutions of said conductor, the windings of the said armature being connected to have current flow through the same in opposite directions, and a collector common to the windings of the armature, substantially as described.

6. In a meter, the combination with an S-shaped field-conductor, of an armature having windings induced by the convolutions of said conductor, the windings of the said armature being connected to have current flow through the same in opposite directions, a commutator common to the windings of the armature, and commutator-brushes for connecting the armature in circuit, substantially as described.

7. In a wattmeter, the combination with a rigid S-shaped field-con-

ductor, of an armature having two windings, each convolution of the field-conductor including a winding, a commutator for the armature, and commutator-brushes for engaging the commutator and including the windings in bridge between the sides of a transmission-circuit, substantially as described.

8. In a wattmeter, the combination with a rigid S-shaped field-conductor, of an armature having two windings, each convolution of the field-conductor including a winding, a commutator for the armature common to the armature-windings, and commutator-brushes for engaging the commutator and including the windings in bridge between the sides of a transmission-circuit, substantially as described.

9. In a wattmeter, the combination with a rigid S-shaped field-conductor, of an armature having two windings, each convolution of the field-conductor including a winding, a commutator common to the windings of the armature and commutator-brushes engaging the commutator for including the armature between the sides of the transmission-circuit, said windings being arranged to have current flow through each in a direction opposite to that flowing in the other, substantially as described.

10. In a meter, the combination with an armature adapted to receive current from a distribution-circuit, of a magnetic corrective device, and means for adjusting the same toward or from the armature, substantially as described.

11. In a meter, the combination with the armature thereof, adapted to receive current from a distribution-circuit, of a magnetic corrective device cooperating with the armature, said corrective device being mounted to rotate about an axis transverse to the axis of rotation of the armature, substantially as described.

12. In a meter, the combination with the armature thereof, formed in two windings or sets of coils, of a single magnetic corrective device having two poles each opposed to a winding of the armature, and means for changing the polarity of the said corrective device with respect to the armature, substantially as described.

13. In a meter, the combination with the armature thereof, formed in two windings or sets of coils, of a single magnetic corrective device having two poles each opposed to a winding of the armature, said corrective device being rotatably mounted to change the polarity of the poles of the corrective device presented to the armature-windings, substantially as described.

14. In a meter, the combination with an armature adapted to receive current from a distribution-circuit and having two windings or sets of coils, of a single magnetic corrective device having two poles each opposed to a winding of the meter, substantially as described.

15. In a meter, the combination with an armature adapted to receive current from a distribution-circuit and having two windings or sets of coils, of a single magnetic corrective device having two poles each opposed to a winding of the meter, the said windings being connected to have current flow through each in a direction opposite to that flowing through the other, substantially as described.

16. In a meter, the combination with a rigid field-conductor, of an armature arranged within the influence of the field-conductor and rotatable journals for the armature, one supported by the rigid conductor, substantially as described.

698,678. ELECTRIC METER. THOMAS DUGAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Jan. 2, 1900. Renewed Jan. 2, 1902. Serial No. 95,000. (No model.)

Claim.—1. The combination with a commutated motor-meter, of a by-path for the commutator of the meter which includes capacity, and adjusting inductance to partially neutralize the capacity, substantially as described.

2. The combination with a motor-meter provided with collector and brush terminals for conveying current to the rotatable member of the meter, of a by-path for said terminals including capacity, and adjusting inductance to partially neutralize the capacity, substantially as described.

3. The combination with a commutated motor-meter including a main brush for contact with the commutator, of a brush supplementing the main brush and included in a by-path about the same, said by-path including capacity, and adjusting inductance to partially neutralize the capacity, substantially as described.

4. In a system of electrical distribution, the combination with a source of current-supplying transmitting device, of a motor-meter having a reversible armature included between the main conductors, a commutator for the armature, main commutator-brushes for engaging the commutator and supplying current to the armature, supplemental commutator-brushes also engaging the commutator and including capacity in circuit therewith, and adjusting inductance to partially neutralize the capacity, substantially as described.

5. In a system of electrical distribution, the combination with a source of current-supplying transmitting device, of a motor-meter having a reversible

ble armature included between the main conductors, a commutator for the armature, main commutator-brushes for engaging the commutator and supplying current to the armature, supplemental commutator-brushes also engaging the commutator, each supplemental brush being included in a by-path about a main brush, and two condensers one in circuit with each supplemental brush, adjusting inductance being included in circuit with each condenser to partially neutralize the capacity, substantially as described.

6. In a system of electrical distribution, the combination with a source of current-supplying transmitting device, of a motor-meter having a reversible armature included between the main conductors, a commutator for the armature, main commutator-brushes for engaging the commutator and supplying current to the armature, supplemental commutator-brushes also engaging the commutator, each supplemental brush being included in a by-path about a main brush, and two condensers, one in circuit with each supplemental brush, each main commutator-brush and the brush supplementing the same simultaneously engaging the same commutator-segment, adjusting inductance being included in circuit with each condenser to partially neutralize the capacity, substantially as described.

7. The combination with a commutated motor-meter, provided with two main brushes for engagement with the commutator, of two additional brushes each supplementing a main brush and included in a by-path, having capacity, about the same, said by-path also including adjusting inductance, substantially as described.

8. The combination with a commutated motor-meter including a main brush for contact with the commutator, of a brush supplementing the main brush and engaging the same commutator, the said brushes being connected at their free ends through capacity, substantially as described.

9. The combination with a commutated motor-meter provided with two main brushes engaging the same commutator, of two additional brushes, each supplementing a main brush, each main brush being united at its free end with the free end of its supplemental brush through capacity, substantially as described.

10. The combination with a commutated motor-meter, of main and supplemental brushes therefor, the latter bearing with greater pressure upon the commutator than the former, capacity being included in circuit with said main and supplemental brushes, substantially as described.

11. The combination with a commutated motor-meter, of main brushes for conveying current thereto, supplemental brushes bearing with greater pressure, upon the same commutator, than the main brushes, each main brush and its supplemental brush engaging the same segment of the commutator, and a condenser connected directly between each main brush and its supplemental brush, substantially as described.

12. The combination with a commutated motor-meter, of main brushes for conveying current thereto, supplemental brushes bearing with greater pressure, upon the same commutator, than the main brushes, and a condenser connected directly between each main brush and its supplemental brush, substantially as described.

13. The combination with a commutated motor-meter, of a wide main brush serving in part to convey current to the meter, and a supplemental brush of smaller width than the main brush and bearing with greater pressure upon the commutator, capacity being included in circuit with said main and supplemental brushes, substantially as described.

14. The combination with a commutated motor-meter, of a wide main brush serving in part to convey current to the meter, and a supplemental brush of smaller width than the main brush and bearing with greater pressure upon the commutator, capacity being included in circuit with said main and supplemental brushes, said main and supplemental brushes engaging the same segment of the commutator, substantially as described.

698,679. ELECTRICAL MEASURING INSTRUMENT. THOMAS DUGAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Jan. 2, 1900. Renewed Dec. 15, 1901. Serial No. 95,000. (No model.)

Claim.—1. In a system of electrical distribution, the combination with a generator supplying current to a transmission-circuit, of a measuring apparatus having a voltmeter-winding connected across the generator-terminals, and a second pressure-winding connected between a point of the transmission-circuit and a second and distant point of the transmission-circuit where the pressure is to be determined to determine the $e r$ drop, whereby the pressure at distant points of the transmission-circuit may be readily determined, substantially as described.

2. In a system of electrical distribution, the combination with a generator supplying current to a transmission-circuit, of a measuring apparatus having a voltmeter-winding connected across the generator-terminals, a second pressure-winding connected between a point of the transmission-circuit and a second and distant point of the transmission-circuit where the pressure is to be determined to determine the $e r$ drop, whereby the pressure at distant points of the transmission-circuit may be readily determined, and a separate measuring element for and compensating with each of said windings, substantially as described.

3. In a system of electrical distribution, the combination with a generator supplying current to a transmission-circuit, of a measuring apparatus having a voltmeter-winding connected across the generator-terminals, a second pressure-winding connected between a point of the transmission-circuit and a second and distant point of the transmission-circuit where the pressure is to be determined, to determine the $e r$ drop, whereby the pressure at distant points of the transmission-circuit may be readily determined, and a switch for opening and closing the circuit through the second winding, substantially as described.

4. In a system of electrical distribution, the combination with a generator supplying current to a transmission-circuit, of a measuring apparatus having a voltmeter-winding connected across the generator-terminals, a second pressure-winding connected between a point of the transmission-circuit and a second and distant point of the transmission-circuit where the pressure is to be determined, to determine the $e r$ drop, whereby the pressure at distant points of the transmission-circuit may be readily determined, a separate measuring element for, and compensating with, each of said windings, and a switch for opening and closing the circuit through the second winding, substantially as described.

5. In a system of electrical distribution, the combination with a generator supplying current to a transmission-circuit, of a measuring apparatus having a voltmeter-winding connected across the generator-terminals,

between points of the circuit having unlike differences of potential, the latter winding being interposed between the sides of the circuit, each circuit of the motor including a movable coil, said coils being mechanically coupled to jointly effect a single measurement, the torques due to the said windings opposing each other, substantially as described.

6. In a system of electrical distribution, the combination with a generator, of a transmission-circuit, a voltmeter having one winding interposed between the generator-terminals and a second winding interposed between points of the circuit having unlike differences of potential, the latter winding being interposed between the sides of the circuit, each circuit of the motor including a movable coil, said coils being mechanically coupled to jointly effect a single measurement, the torques due to the said windings opposing each other, a pointer movable with the windings, and a scale upon which the pointer may indicate measurements, substantially as described.

7. In a system of electrical distribution, the combination with a generator, of a metallic transmission-circuit, and a voltmeter having one winding interposed between the generator-terminals and a second winding interposed between points of the circuit having unlike differences of potential, the latter winding being interposed between the sides of the circuit, substantially as described.

8. In a system of electrical distribution, the combination with a generator, of a metallic transmission-circuit, and a voltmeter having one winding interposed between the generator-terminals and a second winding interposed between points of the circuit having unlike differences of potential, the latter winding being interposed between the sides of the circuit, each circuit of the motor including a movable coil, said coils being mechanically coupled to jointly effect a single measurement, substantially as described.

9. In a system of electrical distribution, the combination with a generator, of a metallic transmission-circuit, and a voltmeter having one winding interposed between the generator-terminals and a second winding interposed between points of the circuit having unlike differences of potential, the latter winding being interposed between the sides of the circuit, each circuit of the motor including a movable coil, said coils being mechanically coupled to jointly effect a single measurement, the torques due to the said windings opposing each other, substantially as described.

10. In a system of electrical distribution, the combination with a generator, of a metallic transmission-circuit, a voltmeter having one winding interposed between the generator-terminals and a second winding interposed between points of the circuit having unlike differences of potential, the latter winding being interposed between the sides of the circuit, each circuit of the motor including a movable coil, said coils being mechanically coupled to jointly effect a single measurement, the torques due to said windings opposing each other, a pointer movable with the windings, and a scale upon which the pointer may indicate measurements, substantially as described.

11. In a system of electrical distribution, the combination with a generator, of a transmission-circuit, and a voltmeter having one winding interposed between the generator-terminals and a second winding interposed between a point of the circuit near the generator and a second, distant point of the transmission-circuit, the latter winding being interposed between the sides of the circuit, substantially as described.

12. In a system of electrical distribution, the combination with a generator, of a transmission-circuit, and a voltmeter having one winding interposed between the generator-terminals and a second winding interposed between a point of the circuit near the generator and a second, distant point of the transmission-circuit, the latter winding being interposed between the sides of the circuit, each circuit of the motor including a movable coil, said coils being mechanically coupled to jointly effect a single measurement, substantially as described.

13. In a system of electrical distribution, the combination with a generator, of a transmission-circuit, and a voltmeter having one winding interposed between the generator-terminals and a second winding interposed between a point of the circuit near the generator and a second, distant point of the transmission-circuit, the latter winding being interposed between the sides of the circuit, each circuit of the motor including a movable coil, said coils being mechanically coupled to jointly effect a single measurement, the torques due to said windings opposing each other, substantially as described.

14. In a system of electrical distribution, the combination with a generator, of a transmission-circuit, a voltmeter having one winding interposed between the generator-terminals and a second winding interposed between a point of the circuit near the generator and a second, distant point of the transmission-circuit, the latter winding being interposed between the sides of the circuit, each circuit of the motor including a movable coil, said coils being mechanically coupled to jointly effect a single measurement, the torques due to the said windings opposing each other, a pointer movable with the windings, and a scale upon which the pointer may indicate measurements, substantially as described.

698,686. ELECTRICAL MEASURING INSTRUMENT. THOMAS DUNN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Jan. 2, 1900. Renewed Dec. 16, 1901. Serial No. 88,990. (No model.)

Claim.—1. In an alternating-current system of electrical distribution, the combination with an alternating-current generator supplying a distribution-circuit, of a pressure-winding interposed between the sides of the circuit, a current-winding, a third winding in inductive relation with the two aforesaid windings, the current-winding serving to divert lines of force due to the pressure-winding from the said third winding into a path parallel with the main path of the pressure lines of force and a voltmeter supplied with current from the said third winding, substantially as described.

2. In a system of alternating-current distribution, the combination with an alternating-current generator supplying a distribution-circuit, of a transformer having three windings, one a pressure-winding interposed between the generator-terminals, the second a current-winding, and the third constituting the secondary of the transformer, the current-winding serving to divert lines of force due to the pressure-winding from the said third winding into a path parallel with the main path of the pressure lines of force and a voltmeter receiving current from the secondary winding, substantially as described.

3. In a system of electrical distribution, the combination with an alternating-current generator supplying a distribution-circuit, of a transformer having three windings and a three-legged core, each of the legs of the core having one of the windings disposed about the same, one of the said windings being a pressure-winding interposed between the sides of the distribution-circuit, the second a current-winding, and the third the secondary of the transformer, the leg of the transformer about which the current-winding is disposed having reluctance to prevent too great a flow of lines of force due to the pressure-winding through this portion of the transformer-core, and a voltmeter receiving current from the secondary of the transformer, substantially as described.

4. In a system of alternating-current distribution, the combination with an alternating-current generator supplying a distribution-circuit, of a transformer having three windings and a three-legged core, each of the legs of the core having one of the windings disposed about the same, one of the said windings being a pressure-winding interposed between the sides of the distribution-circuit, the second a current-winding and the third the secondary of the transformer, the leg of the transformer about which the current-winding is disposed having reluctance to prevent too great a flow of lines of force due to the pressure-winding through this portion of the transformer-core, and a voltmeter receiving current from the secondary of the transformer, substantially as described.

5. In an alternating-current system of electrical distribution, the combination with an alternating-current generator supplying a distribution-circuit, of a pressure-winding interposed between the sides of the circuit, a current-winding, a third winding in inductive relation with the pressure-winding, the current-winding serving to divert lines of force due to the pressure-winding from the said third winding into a path parallel with the main path of the pressure lines of force, and a voltmeter supplied with current from the said third winding, substantially as described.

6. In a system of alternating-current distribution, the combination with an alternating-current generator supplying a distribution-circuit, of a transformer having three windings and a three-legged core, each of the legs of the core having one of the windings disposed about the same, one of the said windings being a pressure-winding interposed between the sides of the distribution-circuit, the second a current-winding and the third the secondary of the transformer, the leg of the transformer about which the current-winding is disposed having an air-gap winding transversely through the same to prevent too great a flow of lines of force due to the

pressure-winding through this portion of the transformer-core, and a voltmeter receiving current from the secondary of the transformer, substantially as described.

698,687. ELECTRICAL MEASURING INSTRUMENT. THOMAS DUNN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Jan. 2, 1900. Renewed Jan. 6, 1902. Serial No. 88,991. (No model.)

Claim.—1. In a system of alternating-current distribution, the combination with an alternating-current generator, of two transformers, one having a primary winding connected in bridge of the distributing-mains at the generator, and the other having its primary winding connected in bridge of the distributing-mains, one of the connections of the latter winding being near the generator and the other being at a point of the transmission-circuit distant from the generator, and a voltmeter, the secondary coils of the transformers being included in series with each other and with the voltmeter-winding, the secondary coils of the transformers being arranged to have the electromotive forces generated therein opposed to each other, substantially as described.

2. In a system of alternating-current distribution, the combination with an alternating-current generator, of two transformers, one having its primary winding connected in bridge of the distributing-mains at the generator, and the other having its primary winding connected in bridge of the distributing-mains, one of the connections of the latter winding being near the generator and the other being at a point of the transmission-circuit distant from the generator, and a voltmeter, the secondary coils of the transformers being included in series with each other and with the voltmeter-winding, substantially as described.

3. In a system of alternating-current distribution, the combination with an alternating-current generator, of two transformers, one having a primary winding connected in bridge of the distributing-mains at the generator, and the other having its primary winding connected between distant points of the transmission system, and a voltmeter, the secondary coils of the transformers being included in series with each other and with the voltmeter-winding, substantially as described.

4. In a system of alternating-current distribution, the combination with an alternating-current generator, of two transformers, one having a primary winding connected in bridge of the distributing-mains at the generator, and the other having its primary winding connected between a point of the transmission-circuit near the generator and a second, distant point of the transmission-circuit, and a voltmeter, the secondary coils of the transformers being included in series with each other and with the voltmeter-winding, substantially as described.

5. In a system of alternating-current distribution, the combination with an alternating-current generator, of two transformers, one having its primary winding connected in bridge of the distributing-mains at the generator, and the other having its primary winding connected in bridge of the distributing-mains, one of the connections of the latter winding being near the generator and the other being at a point of the transmission-circuit distant from the generator, and a voltmeter, the secondary coils of the transformers being arranged to have the electromotive forces generated therein opposed to each other, substantially as described.

6. In a system of alternating-current distribution, the combination with an alternating-current generator, of two transformers, one having its primary winding connected in bridge of the distributing-mains at the generator, and the other having its primary winding connected in bridge of the distributing-mains, one of the connections of the latter winding being near the generator and the other being at a point of the transmission-circuit distant from the generator, and a voltmeter, the secondary coils of the transformers being arranged to have the electromotive forces generated therein opposed to each other, substantially as described.

7. In a system of alternating-current distribution, the combination with an alternating-current generator, of two transformers, one having a primary winding connected in bridge of the distributing-mains at the generator, and the other having its primary winding connected between distant points of the transmission system, and a voltmeter, the secondary coils of the transformers supplying current to the voltmeter-winding, substantially as described.

8. In a system of alternating-current distribution, the combination with an alternating-current generator, of two transformers, one having a primary winding connected in bridge of the distributing-mains at the generator, and the other having its primary winding connected between a point of the transmission-circuit near the generator, and a second, distant point of the transmission-circuit, and a voltmeter, the secondary coils of the transformers supplying current to the voltmeter-winding, substantially as described.

9. In a system of electrical distribution, the combination with a generator supplying the transmission-circuit, of a voltmeter having an operating-winding, and means for subjecting the voltmeter-winding to pressure between the generator-terminals and pressure between a point of the transmission-circuit near the generator and a distant point of the transmission-circuit, substantially as described.

10. In a system of electrical distribution, the combination with a generator supplying the transmission-circuit, of a voltmeter having an operating-winding, and means for subjecting the voltmeter-winding to pressure between the generator-terminals and pressure between distant points of the distribution-circuit, substantially as described.

11. In a system of electrical distribution, the combination with a generator supplying the transmission-circuit, of a voltmeter having an operating-winding, means for subjecting the voltmeter-winding to pressure between the generator-terminals and pressure between a point of the transmission-circuit near the generator and a distant point of the transmission-circuit, and means whereby the said electromotive forces are opposed to produce a resultant electromotive force proportional to the pressure at the distant point to which the said meter-winding is subject, substantially as described.

12. In a system of electrical distribution, the combination with a generator supplying the transmission-circuit, of a voltmeter having an operating-winding, means for subjecting the voltmeter-winding to pressure between the generator-terminals and pressure between distant points of the distribution-circuit, and means whereby the said electromotive forces are opposed to produce a resultant electromotive force proportional to the pressure at the distant point to which the said meter-winding is subject, substantially as described.

698,688. INDUCTION MOTOR-METER. THOMAS DUNN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Jan. 20, 1900. Serial No. 2,101. (No model.)

Claim.—1. In a motor of the class described, the combination with a support for all the moving parts of the motor, of lead-arms from the motor-shaft, clamps adapted to clamp said lead-arms and to be loosened

and moved away therefrom, and binding-posts to which said clamps are attached, substantially as described.

2. In a meter of the class described, the combination with the frame 21, of the limiting-strip 3 secured thereto, receptacle 19 also attached to said frame, a lid 9 for said receptacle, coil, armature and registering-strip carried by said lid, binding-posts supported upon said limiting-strip for connecting the meter with the circuit-conductor, and means for detachably connecting the wire leading to the meter-coils with said binding-posts, substantially as described.

698,689. ELECTRICAL MEASURING INSTRUMENT. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Mar. 2, 1900. Serial No. 7,908. (No model.)

Claim.—1. The combination with an armature provided with core-heads relatively rotatable and movable longitudinally with relation to each other, of armature-wire disposed about the said core-heads, electrically-continuous portions of the armature-winding at the core-heads being displaced laterally, substantially as described.

2. The combination with an armature provided with core-heads relatively rotatable and movable longitudinally with relation to each other, of an armature-wire disposed about the said core-heads, electrically-continuous portions of the armature-winding at the core-heads being displaced laterally, substantially one hundred and eighty degrees, substantially as described.

3. The combination with an armature provided with core-heads relatively rotatable and movable longitudinally with relation to each other, of armature-wire disposed about the said core-heads, electrically-continuous portions of the armature-winding at the core-heads being displaced laterally, substantially one hundred and eighty degrees, and a commutator for conveying current to the armature, substantially as described.

4. The combination with an armature-winding, of a mounting therefor, permitting relative rotation between the ends of said winding, substantially as described.

5. The combination with an armature-winding, of a mounting therefor, permitting relative longitudinal movement of the ends of the armature-winding, substantially as described.

6. The combination with an armature-winding, of a mounting therefor, permitting relative rotation between portions of said winding, substantially as described.

698,690. ELECTRICAL MEASURING INSTRUMENT. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Mar. 2, 1900. Serial No. 7,904. (No model.)

Claim.—1. In a system of distribution, the combination with a source of direct current, of a wattmeter having current and pressure windings receiving current from said source, and a core of commutated magnetizable material for the current-winding, substantially as described.

2. In a system of distribution, the combination with a source of direct current, of a wattmeter having current and pressure windings receiv-

ing current from said source, and a core of commutated magnetizable material for the pressure-winding, substantially as described.

3. In a system of distribution, the combination with a source of direct current, of a wattmeter having current and pressure windings receiving current from said source, and a core of commutated magnetizable material for each of said windings, substantially as described.

4. In an electric meter, the combination with the movable winding thereof, of a commutated core of magnetizable material for said winding, and means for determining the measurement of the meter, substantially as described.

5. In an electric meter, the combination with current and pressure windings, the pressure-winding constituting the armature-winding of the meter of a commutator for conveying the current to the pressure-winding, a core of commutated magnetizable material for said armature-winding, and means for determining the measurement of the meter, substantially as described.

6. In an electric meter, the combination with current and pressure windings, the pressure-winding constituting the armature-winding of the meter of a commutator for conveying the current to the pressure-winding, a core of commutated magnetizable material for the current-winding, and means for determining the measurement of the meter, substantially as described.

7. In an electric meter, the combination with current and pressure windings, the pressure-winding constituting the armature-winding of the meter of a commutator for conveying the current to the pressure-winding, a core of commutated magnetizable material for each of said windings, and means for determining the measurement of the meter, substantially as described.

8. In a wattmeter, the combination with current and pressure windings, of a commutated magnetizable core for the current-winding, substantially as described.

9. In a wattmeter, the combination with current and pressure windings, of a commutated magnetizable core for the pressure-winding, substantially as described.

10. In a wattmeter, the combination with current and pressure windings, of a commutated core of magnetizable material for each of said windings, substantially as described.

698,691. ELECTRICAL MEASURING INSTRUMENT. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Mar. 2, 1900. Serial No. 7,906. (No model.)

Claim.—1. In an alternating-current meter, the combination with a measuring element, of windings for causing an extension of said measuring element, said extension being proportional to the true watts and to the magnetizing component, a portion of said windings being carried by said measuring element, and means for limiting the action of the said windings to cause an extension of the said measuring element proportional to the true watts or to the magnetizing component, substantially as described.

2. In an alternating-current meter, the combination with a measuring element, of two sets of windings, each comprising a current and a pressure winding for causing an extension of the measuring element said extension being proportional to the true watts and to the magnetizing component, a portion of said windings being carried by said measuring element, and switching means adapted to control the continuity of circuit connections for limiting the measuring element to the action of one of the windings, substantially as described.

3. In an alternating-current meter, the combination with a measuring element, of pressure and current field-windings for causing an extension of the said measuring element said extension being proportional to the true watts and to the magnetizing component, a portion of said windings being carried by said measuring element, and switching means adapted to control the continuity of circuit connections for limiting the extension of said measuring element proportional to either the true watts or to the magnetizing component, substantially as described.

4. In an alternating-current meter, the combination with a measuring element, of pressure and current field-windings for producing torque upon the measuring element proportional to the true watts and to the magnetizing component, a portion of said windings being carried by said measuring element, and means for permitting said element to be subjected to either torque alone, substantially as described.

5. In an alternating-current meter, the combination with a measuring element, of pressure and current field-windings for producing torque upon the measuring element proportional to the true watts and to the magnetizing component, a portion of said windings being carried by said measuring element, and means for limiting the measuring element to the action of one of the torques, substantially as described.

6. In an alternating-current meter, the combination with means for producing two pressure fields substantially in quadrature with each other, of means for producing a third field varying in phase with the current, a movable measuring element carrying a portion of the windings of the meter, and means whereby said measuring element may be subjected to the action of the current field and one pressure field only, substantially as described.

7. In an alternating-current meter, the combination with means for producing two pressure fields substantially in quadrature with each other, of means for producing a third field varying in phase with the current, a movable measuring element supporting the windings for causing the pressure fields, and means whereby said measuring element may be subjected to the action of the current field and one pressure field only, substantially as described.

8. In an alternating-current meter, the combination with means for producing two pressure fields substantially in quadrature with each other, of means for producing a third field varying in phase with the current, a movable measuring element, said measuring element carrying the windings for producing the pressure fields, the latter field in cooperation with one of the pressure fields serving to extend said measuring element to determine the true watts and in cooperation with the other field to move said element to determine the magnetizing component, and means whereby said element may be subjected to the action of either one only of said torques, substantially as described.

9. In a system of alternating-current distribution, the combination with an alternating-current generator, of a movable element, electromagnetic means receiving current from said generator for causing two torques upon said element respectively proportional to the true watts and the magnetizing component, a portion of said electromagnetic means being carried by said movable element, and means whereby said element may be subjected to either of said torques, substantially as described.

10. In a system of alternating-current distribution, the combination with an alternating-current generator, of a movable element, electromagnetic means receiving current from said generator for causing two torques

upon said element respectively proportional to the true watts and the magnetizing component, a portion of said electromagnetic means being carried by said movable element, and means whereby said element may be subjected to one only of said torques, substantially as described.

11. In a system of alternating-current distribution, the combination with an alternating-current generator, of a movable element, and electromagnetic means receiving current from said generator for causing two torques upon the movable element, one of said torques being capable of causing movement of said element proportional to the true watts, and the other, movement of said element proportional to the magnetizing component of the alternating current, and means whereby said element may be subjected to either one only of said torques, substantially as described.

12. In an alternating-current meter, the combination with a measuring element, of electromagnetic means adapted in cooperation with said measuring element to measure the true watts in an alternating-current circuit, a second electromagnetic torque-producing means adapted, in cooperation with said measuring element, to measure the wattless component in an alternating-current circuit, a portion of said electromagnetic means being carried by said measuring element, and means for bringing the torque-producing means into and out of effective association with the measuring element, substantially as described.

13. In an alternating-current meter, the combination with a measuring element, of an electromagnetic torque-producing means adapted, in cooperation with said measuring element, to measure the true watts in an alternating-current circuit, a second electromagnetic torque-producing means adapted, in cooperation with said measuring element, to measure the wattless component in an alternating-current circuit, a portion of said electromagnetic means being carried by said measuring element, and means for bringing each torque-producing means into and out of effective association with said measuring element, substantially as described.

14. In a meter for alternating-current circuits provided with relatively movable members in combination, means for producing a torque between said members proportional to the real watts of the current flowing in said circuit, means for producing between said members a second torque proportional to the wattless component of said current, and means whereby the meter may be subject to one of said torques alone, substantially as described.

15. In a meter for alternating-current circuits in combination, a series winding or windings, a plurality of short-windings inductively related thereto, means for causing a current to flow in one of said short-windings in phase with the electromotive force of the circuit, means for causing a current to flow in another of said windings in quadrature with said electromotive force, and means permitting the flow of current through one of the said short-windings alone, substantially as described.

16. In a meter for alternating-current circuits in combination, a series winding or windings, a plurality of short-windings inductively related thereto, means for causing a current to flow in one of said short-windings in phase with the electromotive force of the circuit, means for causing a current to flow in another of said windings in quadrature with said electromotive force, means for permitting the flow of current through one of the said short-windings alone, and a common support for the short-windings, movable with respect to said series winding or windings, substantially as described.

698,692. ELECTRICAL MEASURING INSTRUMENT. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Filed Mar. 2, 1900. Serial No. 7,905. (No model.)

Claim.—1. In an oscillating meter, the combination with the movable element thereof, of an oscillating circuit-changing switch for changing circuit connections of the meter, a segmental gear, an electromagnetic device for controlling the operation of said circuit-changing switch provided with an armature carrying the said segmental gear, a measuring device actuated by said armature, a piston carried by the circuit-changing switch in engagement with the said segmental gear, and means controlled by the oscillating member of the meter for governing the operation of the said electromagnetic device, substantially as described.

2. In an oscillating meter, the combination with the movable element thereof, of an oscillating circuit-changing switch for changing circuit connections of the meter comprising four segmental contacts and four brushes engaging the same, two of the said brushes being positioned in contact with two contact-segments, the remaining brushes being adapted to make contact alternately with each of the remaining contact-segments, the latter segments being electrically connected each with one of the abutment segments, a pivotally-mounted armature for actuating said circuit-changing switch, and a measuring device actuated thereby, substantially as described.

3. In an oscillating motor, the combination with the movable element thereof, of an oscillating circuit-changing switch for changing the circuit connections of the motor, an electromagnetic device for controlling the operation of said circuit-changing switch, a suitably-mounted armature provided with means for operatively engaging the said oscillatory circuit-changing switch, a measuring device actuated by said armature, and means controlled by said oscillating member of the motor for governing the operation of the said electromagnetic device, substantially as described.

698,698. ELECTRIC METER. THOMAS DUNNAN, Chicago, Ill., assignor to the Siemens & Halske Electric Company of America, Chicago, Ill., a Corporation of Illinois. Original application filed Apr. 11, 1900. Serial No. 677,119. Divided and this application filed Mar. 1, 1901. Serial No. 69,304. (No model.)

Claim.—1. The method of producing a magnetic field to quadrature with the line or impressed electromotive force, which consists in lagging a derived current, dividing said current and producing thereby two independent magnetic fields, and combining said magnetic fields to form a resultant magnetic field of the required phase relation, substantially as described.

2. The method of producing motion and regulating the same, which consists in producing a field proportional to the current, producing two out-of-phase fields by two pressure-windings receiving current independently of each other, subjecting a movable armature to the action of the said fields and effecting a relative adjustment between the windings producing said out-of-phase fields, substantially as described.

698,694. ZINC OXALATE COMPOUND. ARTHUR BARNHART and ROBERT BARNHART, Hartford, Germany, assignors to Farbwerke of Höchst a. M., New York, N. Y., a Corporation of New York. Filed Oct. 20, 1901. Serial No. 69,422. (No specimens.)

Claim.—1. The herein-described new pharmaceutical product derived from gallic acid and zinc compounds being, when dry and pulverized, amorphous yellowish-colored powder soluble in water with a yellowish color, and insoluble in ether, in benzene and in chloroform, substantially as described.

2. The herein-described specific derivative of gallic acid containing

zinc, obtainable from gallic acid and zinc chloride, being, when dry and pulverized, a yellowish-white powder readily soluble in water, soluble in dilute alcohol and dilute acetic acid and being insoluble in ether, benzene and chloroform, substantially as described.

698,695. BALD-TIE MACHINE. RICHARD J. BAY, Two Rivers, Wis. Filed Oct. 31, 1901. Serial No. 69,606. (No model.)

Claim.—1. In a machine for making bald-ties, the combination of the revolving shaft, a lower jaw carried thereby, an upper clamping-jaw movable with respect to the lower jaw, shaping-plates carried by each of said jaws and adapted to engage with and entirely surround the partly-formed knot, and a vice or clamp adapted to hold the ends of the wire during the rotations of the clamping-jaws, substantially as specified.

2. In a machine for making bald-ties, the combination with a revolving shaft, of a clamping-jaw secured to said shaft, an upper clamping-jaw movable with respect to the lower jaw, a spring for closing said jaws, shaping-plates carried by each of said jaws and adapted to engage with and entirely surround the partly-formed knot, and a vice or clamp adapted to hold the ends of the wire during the rotations of the clamping-jaws.

3. In a machine for making wire bald-ties, the combination of the revolving shaft, a clamping-jaw secured thereto, an upper movable jaw, shaping-plates carried by each of said jaws, an operating-lever pivoted to the lower jaw and operatively connected to the upper jaw, a spring extending between said lever and the lower jaw and tending to close the jaws, and a vice or clamp adapted to hold the ends of the wire during the twisting operation.

4. In a machine for making wire bald-ties, the combination of the revolving shaft, a clamping-jaw secured thereto, an upper movable jaw, shaping-plates carried by each of said jaws, one of said plates being provided with a guiding-tongue and the other with a receiving socket or slot for said tongue, and a vice or clamp for holding the ends of the wire during the twisting operation.

5. In a machine for making wire bald-ties, the combination of the revolving shaft, a lower clamping-jaw secured thereto, an upper movable jaw, means for moving said jaws to open or closed position, a stationary inclined clamping-finger carried by the lower jaw and adapted to engage the inclined face of the upper jaw, and a vice or clamp for holding the ends of the wire during the twisting operation.

6. In a machine for making wire bald-ties, the combination of the revolving shaft, a lower clamping-jaw secured thereto, an upper movable jaw, a fixed handle carried by the upper jaw, a lever pivoted to the lower jaw and having a handle portion in proximity to the stationary handle, a spring-catch carried by one of said handles and adapted to engage with the opposite handle, means for operatively connecting the lever to the upper jaw, a spring carried by said lever and adapted to move said upper jaw to closed position, and a vice or clamp for holding the ends of the wire during the twisting operation.

7. In a machine for making wire bald-ties, the combination of the revolving shaft, a lower clamping-jaw secured thereto, an upper movable jaw, a plate-spring carried by the lower jaw and in operative contact with the top of the upper jaw, means for opening and closing said jaws, and a vice or clamp for holding the ends of the wire during the twisting operation.

698,696. PROCESS OF MAKING PARI-GREEN. EDWARD FRANKLIN, Hingham Falls, N. Y. Filed Aug. 17, 1901. Serial No. 73,045. (No specimens.)

Claim.—1. The process of making pari-green, which consists in electrolyzing with a copper anode a solution of an acetate and arsenious acid.

2. The process of making pari-green, which consists in passing an electric current through a solution of an acetate and arsenious acid with a copper anode and with the cathode immersed in a solution of acetate and isolated to prevent the cathode products mixing with the arsenious acid of the electrolyte.

698,696.

698,697. WATER-TUBE BOILER. STUART E. FREEMAN, St. Louis, Mo. Filed Apr. 30, 1900. Serial No. 14,931. (No model.)

Claim.—1. In a water-tube boiler, the combination of a pair of heads, water-supply and steam pipes each having connection to both of said heads, field-tubes and circulating-tubes connected in independent sets to said heads, and a superheater-coil connected to said steam-pipe and arranged above said circulating and field tubes, substantially as described.

2. In a boiler for water-tube boilers, the combination of two sections provided with interior ribs, a partition-plate located between said sections, and stud-bolts inserted into said ribs by which the sections are bound together, substantially as described.

698,698. IGNITION MATERIAL FOR MATCHES. ROBERT E. A. GARR, Rainbow, Germany. Filed Dec. 31, 1900. Serial No. 69,932. (No specimens.)

Claim.—1. An ignition material composed of a salt of a polybasic acid and a substance which readily yields oxygen, substantially as described.

2. An ignition material composed of a salt of tetrabasic acid and a substance which readily yields oxygen, substantially as described.

698,699. TRACTION DRIVER. PAUL L. GOWLA, Seattle, Wash., assignor to the Gould Traction Car Company, Seattle, Wash., a Corporation of Washington. Filed Apr. 16, 1901. Serial No. 69,944. (No model.)

Claim.—1. In a device of the nature indicated; the combination with a platform; of a plurality of movable legs, laterally-projecting bear-

ing-blocks on said legs, and upper and lower bearing-surfaces longitudinally the platform respectively cooperating with said blocks to support respective legs for advancement on the platform and the platform for progressive movement on a supporting set of said legs.

2. In a device of the nature indicated; the combination with a platform; of a plurality of movable legs arranged in sets and having laterally-projecting bearing-surfaces, upper and lower bracket-surfaces longitudinally the platform and mechanism operatively connected with said platform and legs to place and advance said sets of legs successively on said upper surface and to move said platform progressively with said lower surface resting on the bearing-blocks of preceding legs.

3. In a device of the nature indicated; the combination with a platform; of a plurality of movable legs, means cooperatively connecting said platform and legs to support the platform for progressive movement on preceding legs and succeeding legs for advancement on the platform and means to elevate and lower the unsupporting legs from and to the traction-surfaces.

4. In a device of the nature indicated; the combination with a platform; of a plurality of movable legs, bearing-blocks on said legs and brackets on the platform cooperating with said blocks to alternately support the platform for progressive movement on planted legs and unplanted legs for advancement on the platform.

5. In a device of the nature indicated; the combination with a platform; of a plurality of movable legs, laterally-projecting bearing-blocks on said legs and brackets fixed on said platform each having an endless bearing-surface cooperating with a respective block to support the platform for progressive movement on planted legs and unplanted legs for advancement on the platform.

6. In a device of the nature indicated; the combination with a platform having a series of longitudinally-disposed parallel guide-slots adjacent each side edge; of legs movably engaged with said guides, and having laterally-projecting bearing-blocks and the disposed longitudinally said platform connecting the legs in pairs, brackets fixed to said platform having endless bearing-surfaces for said blocks, parallel said guides and endless bolts mounted on said platform in conformity to said bearing-surfaces and operatively connected to respective legs.

7. In a device of the nature indicated; the combination with a platform having a series of longitudinally-disposed parallel guide-slots adjacent each corner; of legs movably engaged with said guides and having laterally-projecting bearing-blocks and feet disposed longitudinally said platform connecting the legs in pairs, brackets fixed to said platform having upper and lower bearing-surfaces for the blocks, endless flat bolts mounted on said platform parallel said bearing-surfaces and operatively connected to respective legs.

8. In a device of the nature indicated; the combination with a platform having a series of longitudinally-disposed parallel guide-slots adjacent each corner; of legs movably engaged with said guides and having laterally-projecting bearing-blocks and feet disposed parallel said slots and

using the legs in pairs, brackets fixed to said platform having upper and lower bearing-surfaces for the blocks, chains which are mounted at opposite ends of each slot, endless link belts on said wheels operatively connected to respective legs and means to supply motive energy to a wheel of each pair of legs.

2. In a device of the nature indicated the combination of a platform 1 having slots 5, legs 3 movable in the slots connected in pairs, by feet 6 and having bearing-rollers 4 journaled thereon, brackets 5 for said rollers parallel said slots, belts 7 mounted parallel said brackets and connected to the legs and suitable means to drive a belt of each pair of legs.

698,700. PROCESSING-MACHINE. ALBERT GRAYMAN, Detroit, Ill. Assignor to Arthur G. Leonard, trustee, Chicago, Ill. Filed May 28, 1898. Serial No. 598,546. (No model.)

Claim.—1. In a pegging-machine, the combination of a rotating horn carrying an arvil, the said arvil being provided with a slot extending wholly across the face; and means adapted to retain the slot in proper position to the line of pegs, and the feeding of the sheet, notwithstanding the rotation of said horn on its axis in pegging the sheet, substantially as, and for the purposes, set forth.

2. In a pegging-machine, the combination with a rotating horn carrying an arvil, the said arvil being provided with a slot extending wholly across the face; and means adapted to retain the slot in proper position to the line of pegs, and the feeding of the sheet, notwithstanding the rotation of said horn on its axis in pegging the sheet, substantially as, and for the purposes, set forth.

3. The combination of the rotatable horn of a pegging-machine, with the arvil arranged non-coincident with the axis of rotation of the horn, said arvil having a feed movement from one to the other side of and through the axis of the horn, substantially as described.

4. The combination of the rotatable horn of a pegging-machine, with a work-supporting arvil pivotally supported in the tip thereof and provided with an arvi-passageway having both the ends of its operative portion non-coincident with the axis of rotation of the horn and means for preventing rotation of the arvil when the horn is turned, substantially as described.

5. The combination of the rotatable horn of a pegging-machine, with a work-supporting arvil pivotally supported in the tip thereof and provided with an arvi-passageway having both the ends of its operative portion non-coincident with the axis of rotation of the horn, the non-rotatable but vertically-movable treadle-rod or horn-post passing through said horn, a treadle connected to said treadle-rod, and connections between the arvil and the upper end of said treadle-rod for preventing rotation of the arvil when the horn is turned, substantially as described.

6. The combination of the rotatable horn of a pegging-machine, with a work-supporting arvil pivotally supported in the tip thereof and provided with an arvi-passageway having both the ends of its operative portion non-coincident with the axis of rotation of the horn, the non-rotatable but vertically-movable treadle-rod or horn-post passing through said horn, a treadle connected to said treadle-rod, and connections between the arvil and the upper end of said treadle-rod for preventing rotation of the arvil when the horn is turned, substantially as described.

7. The combination of the rotatable horn of a pegging-machine, consisting of the device, the substantially vertical portion, and the inclined portion, with a work-supporting arvil pivotally supported in the tip thereof and provided with an arvi-passageway having both the ends of its operative portion non-coincident with the axis of rotation of the horn, the non-rotatable but vertically-movable treadle-rod or horn-post passing through said horn, and connections between said treadle-rod and arvil comprising the gear on the arvil and the end of the treadle-rod, and the rods U and V geared thereto, for preventing the rotation of the arvil when the horn is turned, substantially as shown and described.

8. In a pegging-machine, the combination of a rotatable horn, with the work-supporting arvil pivotally supported in the tip thereof and provided with an arvi-passageway having both the ends of its operative portion non-coincident with the axis of rotation of the horn, and peg cutting, driving and feeding mechanism, the arvil of said mechanism being arranged non-coincident with the axis of rotation of said horn, and having a feed movement from one to the other side of the axis of the horn, substantially as described.

9. In a pegging-machine, the combination of the rotatable horn, with the work-supporting arvil pivotally supported in the tip thereof and provided with an arvi-passageway having both the ends of its operative portion non-coincident with the axis of rotation of the horn, means for preventing rotation of the arvil when the horn is turned, and peg cutting, driving and feeding mechanism, the arvil of said mechanism being arranged non-coincident with the axis of rotation of said horn, and having a feed movement from one to the other side of the axis of the horn, substantially as described.

698,701. MACHINE FOR CAPPING AND COMPLETING CANS. HENRY L. GUNTERMAN, Chicago, Wash. Filed Jan. 20, 1900. Serial No. 2,146. (No model.)

Claim.—1. A machine of the class described, comprising an intermittently-rotating and vertically-movable plate for carrying the can bodies and heads, means for engaging and revolving the can bodies and heads in the plate, means for imparting a vertical movement to the plate, and means for crimping and compressing the can-flanges while the can body and head are being rotated, substantially as shown and described.

2. A machine of the class described, comprising an intermittently-rotating and vertically-movable plate for carrying the can bodies and

heads, means for revolving the can body and head in the plate, means for imparting a vertical movement to the plate, and a crimping-roller having its peripheral surface formed with an angular groove for engaging the can-flanges and crimping the same while the body revolves to form a double seam, substantially as described.

3. A machine of the class described, comprising an intermittently-rotating and vertically-movable plate having retaining means for holding the can bodies and heads and for allowing the same to be revolved in the plate, means for engaging the can body and head to revolve the same in said retaining means, means for imparting a vertical movement to the said plate, a crimping-roller having its peripheral surface formed with an angular groove for engaging the can-flanges to crimp the same while the can body and head are being rotated, the said angular groove causing the flanges to turn downward and toward to form a double seam, and a compressing-roller to compress the seam previously formed by the said crimping-roller, substantially as shown and described.

4. A machine of the class described, comprising an intermittently-rotating and vertically-movable plate having retaining means for holding the can bodies and heads and for allowing the same to be revolved in the plate, a plurality of devices for successively engaging the can body and head to clamp and to rotate the same, means for imparting a vertical movement to the plate, a crimping-roller for engagement with one of the can-flanges to crimp the same and operating in conjunction with one of the said clamping and rotating devices, and a compressing-roller operating in conjunction with the other clamping and rotating device for engaging and compressing the seam formed by the said crimping-roller, substantially as shown and described.

5. A machine of the class described, comprising an intermittently-rotating can-body-revolving plate having retaining means for holding the body and allowing the same to be revolved in the said means, a can-head-revolving plate having intermittent motion in unison with the said can-revolving plate, and adapted to register therewith to bring a can-head over a can-body, and a reciprocating plunger for engaging the can-head and pressing the same out of the can-head-revolving plate onto the end of the can-body, and a table under the registering portion of the said plates, to sustain the can-body while the can-head is forced upon it by the said plunger, substantially as shown and described.

6. A machine of the class described, comprising an intermittently-rotating can-body-revolving plate having retaining means for holding the body and allowing the same to be revolved in the same means, a can-head-revolving plate having intermittent motion in unison with the said can-revolving plate, and adapted to register therewith to bring a can-head over a can-body, a reciprocating plunger for engaging the can-head and pressing the same out of the can-head-revolving plate onto the end of the can-body, and a table under the registering portion of the said plates, to sustain the can-body while the can-head is forced upon it by the said plunger, substantially as shown and described.

7. A machine of the class described, comprising an intermittently-rotating and vertically-movable can-body-revolving plate, having notches in its periphery and retaining means for holding a can-body in a notch, and for allowing the said can-body to be turned in the said notch, a revolvable support, a revolvable spindle in alignment with the said support and both in alignment with a plate-notch, to engage the can body and head at the bottom and top and revolve the same, means for rotating the support and spindle in unison, means for raising the plate and a crimping-roller for engagement with the flanges of the can body and head, the said crimping-roller having its peripheral surface formed with an angular groove, substantially as shown and described.

8. A machine of the class described, comprising an intermittently-rotating can-body-revolving plate, having notches in its periphery and retaining means for holding a can-body in a notch, and for allowing the said can-body to be turned in the said notch, a revolvable support, a revolvable spindle in alignment with the said support and both in alignment with a plate-notch, to engage the can body and head at the bottom and top and revolve the same, means for rotating the support and spindle in unison, means for raising the plate and a crimping-roller for engagement with the flanges of the can body and head, and means for imparting a reciprocating motion to the said plate in an axial direction, substantially as shown and described.

9. A machine of the class described, comprising an intermittently-rotating can-body-revolving plate, having notches in its periphery and retaining means for holding a can-body in a notch, and for allowing the said can-body to be turned in the said notch, a revolvable support, a revolvable spindle in alignment with the said support and both in alignment with a plate-notch, to engage the can body and head at the bottom and top and revolve the same, means for rotating the support and spindle in unison, a crimping-roller for engagement with the flanges of the can body and head, and means for imparting a reciprocating motion to the said plate in an axial direction, the said means comprising a roller loosely mounted in the shaft, a stop on said shaft with which the roller engages, a lever carrying said roller, and means for crimping the lever, substantially as shown and described.

10. A machine of the class described, comprising an intermittently-

rotating can-body-revolving plate, having notches in its periphery and retaining means for holding a can-body in a notch, and for allowing the said can-body to be turned in the said notch, a revolvable support, a revolvable spindle in alignment with the said support and both in alignment with a plate-notch, to engage the can body and head at the bottom and top and revolve the same, means for rotating the support and spindle in unison, a crimping-roller for engagement with the flanges of the can body and head, means for raising the plate and means for imparting a yielding pressure on the said crimping-roller, substantially as shown and described.

11. A machine of the class described, comprising an intermittently-rotating can-body-revolving plate, having notches in its periphery and retaining means for holding a can-body in a notch, and for allowing the said can-body to be turned in the said notch, a revolvable support, a revolvable spindle in alignment with the said support and both in alignment with a plate-notch, to engage the can body and head at the bottom and top and revolve the same, means for rotating the support and spindle in unison, a crimping-roller for engagement with the flanges of the can body and head, and a rod held to reciprocate in the said spindle to press the said can-head, substantially as shown and described.

12. A machine of the class described, comprising an intermittently-rotating can-body-revolving plate, having notches in its periphery and retaining means for holding a can-body in a notch, and for allowing the said can-body to be turned in the said notch, a revolvable support, a revolvable spindle in alignment with the said support and both in alignment with a plate-notch, to engage the can body and head at the bottom and top and revolve the same, means for rotating the support and spindle in unison, a crimping-roller for engagement with the flanges of the can body and head, and a rod held to reciprocate in the said spindle to press the said can-head, a roller loosely surrounding the spindle-shaft, a ring mounted to turn loosely in said roller, a bar secured to the rod near the upper end and extending through vertically-disposed slots in the spindle-shaft, the said bar being held in the said ring, a lever carrying said roller, and means for imparting a crimping movement to said lever to impart a periodical reciprocation to the said rod, substantially as shown and described.

13. A machine of the class described, comprising an intermittently-rotating can-body-revolving plate, having notches in its periphery and retaining means for holding a can-body in a notch, and for allowing the said can-body to be turned in the said notch, a revolvable support, a revolvable spindle in alignment with the said support and both in alignment with a plate-notch, to engage the can body and head at the bottom and top and revolve the same, means for rotating the support and spindle in unison, a crimping-roller for engagement with the flanges of the can body and head, mechanism for raising the plate, a lever carrying the said crimping-roller, a cam connection for the said lever, and a spring in the said connection, for imparting a yielding pressure on the said lever and its crimping-roller, substantially as shown and described.

14. In a machine of the class described, a receiving-plate, a clamping-ring carried by said plate, and having a seat for the can-head, the said clamping-ring being arranged to hold the assembled can body and head and to permit of turning the same in the clamping-ring, a device for rotating the can body and head for crimping purposes, the said device comprising a revolvable support, a revolvable spindle in alignment with the said support, and held against axial movement, means for raising the plate to bring the top of the can-head against the under surface of the spindle, means for reciprocating the support to move it in contact with the bottom of the can to hold the can-head in contact with the spindle when the plate is returned to its normal or lower position, means for rotating the support and spindle in unison, and a rod slidable in the said spindle and adapted to engage the top of the can-head to push the can-head into its seat in the clamping-ring, on the receding of the support, substantially as shown and described.

15. In a machine of the class described, a device for rotating the assembled can body and head for crimping purposes, the said device comprising a revolvable support, a revolvable spindle in alignment with the said support and held against axial movement, means for reciprocating the said support to cause the same to engage the bottom of the can, and hold the head of the can in contact with the spindle, means for rotating the support and spindle, and a rod slidable in the said spindle and adapted to engage the can-head to move the can body and head out of a clamping position on the receding of the support, a bar secured to the upper end of said rod and extending through slots in the spindle-shaft, a roller loosely surrounding the shaft and connected with the said bar, a lever carrying the said roller, and means for crimping the lever to impart a yielding motion to the said rod, substantially as shown and described.

16. A machine of the class described, comprising an intermittently-rotating and vertically-movable can-body-revolving plate, having notches in its periphery and retaining means for holding a can-body in a notch and for allowing the can-body to be turned in the said notch, means for moving the plate in an axial direction, a device having two rotatable members, one of which is held against axial movement and the other is

mounted to slide axially to clamp the can body and head between the members and rotate the same in the plates, a collar mounted loosely on the lower end of the axially-movable member, a stop on said member for holding the said collar against axial movement on the said member and means connected with the said collar for moving the same to impart a sliding motion to the said member, substantially as shown and described.

17. A machine of the class described, comprising an intermittently-rotatable and axially-movable plate having retaining means for holding the can bodies and heads and for allowing the same to be revolved in the plates, means for moving the plates in an axial direction a device having two rotatable members one of which is held against axial movement and the other is mounted to slide axially to clamp an assembled can body and head between the members and to rotate the same in the plates, a collar mounted loosely on the lower end of the axially-movable member and held against sliding movement thereon, a rock-shaft provided with arms having pins carrying the said collar, means for moving the said rock-shaft to impart an up-and-down sliding motion to the said axially-movable member, and a roller for engaging the edges of the can for crimping and compressing purposes, substantially as shown and described.

18. A machine of the class described, comprising an intermittently-rotating and axially-movable plate having retaining means for holding the can-bodies and can-heads and for allowing the same to be revolved in the plates, means for imparting motion to the plates in an axial direction, a device having two rotatable members, one of which is mounted to slide axially to clamp the assembled can body and head between the members and to rotate the same in the plates, means for imparting a sliding motion to the said axially-movable member, and an axially-movable member in the non-axially-movable member, for moving the can body and head out of a clamping position, substantially as shown and described.

19. A machine of the class described, comprising a plate or carrier, for carrying the assembled can-body and can-head, a plurality of devices for successively engaging the can-body and head to clamp and to rotate the same, a crimping-roller for engaging the flanges of the can body and head, to crimp the said flanges, the crimping-roller operating in conjunction with one of the said clamping and rotating devices, and a compression-roller operating in conjunction with the other clamping and rotating device, to compress the seam previously formed by the said crimping-roller, substantially as shown and described.

20. A machine of the class described, comprising a plate or carrier, for carrying the assembled can-body and can-head, a plurality of devices for successively engaging the can body and head to clamp and to rotate the same, a crimping-roller for engaging the flanges of the can body and head, to crimp the said flanges, the crimping-roller operating in conjunction with one of the said clamping and rotating devices, a compression-roller operating in conjunction with the other clamping and rotating device, to compress the seam previously formed by the said crimping-roller, and means, substantially as described, for holding the said crimping-roller and the said compression-roller with a yielding pressure against the flanges and seam, as set forth.

21. A machine of the class described, comprising a plate or carrier, for carrying the assembled can-body and can-head, a plurality of devices for successively engaging the can body and head to clamp and to rotate the same, a crimping-roller for engaging the flanges of the can body and head, to crimp the said flanges, the crimping-roller operating in conjunction with one of the said clamping and rotating devices, a compression-roller operating in conjunction with the other clamping and rotating device, to compress the seam previously formed by the said crimping-roller, and means for imparting intermittent rotary motion to the said plate or carrier, to bring a crimped can from one of the said devices to the other, substantially as shown and described.

22. A machine of the class described, comprising a plate or carrier, for carrying the assembled can-body and can-head, a plurality of devices for successively engaging the can body and head to clamp and to rotate the same, a crimping-roller for engaging the flanges of the can body and head, to crimp the said flanges, the crimping-roller operating in conjunction with one of the said clamping and rotating devices, a compression-roller operating in conjunction with the other clamping and rotating device, to compress the seam previously formed by the said crimping-roller, means for imparting an intermittent rotary motion to the said plate or carrier, to bring a crimped can from one of the said devices to the other, and a locking device and means for operating the same and locking the said plate in position during the period of rest, substantially as shown and described.

23. A machine of the class described, provided with a plate having peripheral notches, and retaining devices in the said notches to hold a can-body in position in the notch, each of the said retaining devices consisting of an open clamping-ring secured to the plate at the notch, and a spring-pressed clamping bolt or bolt displace in the ring, the latter having its round ends flush with the opposed corners of the notch-wall, substantially as shown and described.

24. A machine of the class described, provided with a plate having peripheral notches, and retaining devices in the said notches to hold a can-body in position in the notch, the said retaining devices each comprising an open clamping-ring secured to the plate at the notch, and having a segmental recess formed in its upper part to receive the can-head, and a groove in the lower portion at its inner face, slidable and spring-pressed clamping-bolt arranged in the upper portion of said ring and projecting into said segmental recess, and a spring held in said groove and projecting on each side of the clamping-ring to engage the surface of the can-body, substantially as shown and described.

25. A machine of the class described, comprising a can-body-receiving plate having retaining devices for the can-bodies, a feeding device for automatically feeding the can-bodies successively to the said retaining device, means for intermittently rotating the said plate and in unison with the movement of the said retaining parts of the said feeding device, and a conveying mechanism for carrying the can-bodies to the said feeding device, said conveying device having retaining members operating in unison with the feeding device, to allow a can-body at a time to pass to the feeding device, substantially as shown and described.

26. A machine of the class described, comprising a can-body-receiving plate having retaining devices for the can-bodies, a feeding device for automatically feeding the can-bodies successively to the said retaining device, means for intermittently rotating the said plate and in unison with the movement of the said retaining parts of the said feeding device, and an ejecting device operating in unison with the said feeding device, to eject a finished can at a time from the said plate while the latter is at rest, substantially as shown and described.

27. A machine of the class described, comprising a can-body-receiving plate having retaining devices for the can-bodies, a feeding device for automatically feeding the can-bodies successively to the said retaining device, means for intermittently rotating the said plate and in unison with the movement of the said retaining parts of the said feeding device, a can-head-feeding device, a can-head-receiving plate for bringing a can-head over a can-body in the said can-body-receiving plate, and a pusher for pushing a can-head at a time from the said can-head-feeding device onto the said can-head-receiving plate, the said pusher operating in unison with the said feeding device, substantially as shown and described.

28. A machine of the class described, comprising a can-body-receiving plate having retaining devices for the can-bodies, a feeding device for automatically feeding the can-bodies successively to the said retaining device, means for intermittently rotating the said plate and in unison with the movement of the said retaining parts of the said feeding device, a can-head-feeding device, a can-head-receiving plate for bringing a can-head over a can-body in the said can-body-receiving plate, a pusher for pushing a can-head at a time from the said can-head-feeding device onto the said can-head-receiving plate, the said pusher operating in unison with the said feeding device, and an ejecting device for removing a finished can from the said plate and operating in unison with the said feeding device and the said pusher, substantially as shown and described.

29. A machine of the class described, comprising a can-body-receiving plate having retaining devices for the can-bodies, a feeding device for automatically feeding the can-bodies successively to the said retaining device, means for intermittently rotating the said plate and in unison with the movement of the said retaining parts of the said feeding device, a can-head-feeding device, a can-head-receiving plate for bringing a can-head over a can-body in the said can-body-receiving plate, a pusher for pushing a can-head at a time from the said can-head-feeding device onto the said can-head-receiving plate, the said pusher operating in unison with the said feeding device, a retaining and releasing device for the heads on the said can-head-feeding device and controlled by the can-bodies on passing from the conveying device to the can-body-feeding device, substantially as shown and described.

30. A machine of the class described, having a can-head-feeding device, a can-head-receiving plate, and feeding device comprising a revolving disk upon which the can-heads are placed, a stopping and releasing device for holding the can-head temporarily stationary while the disk revolves, and a pushing-head for pushing a released head into the said plate, substantially as shown and described.

31. A machine of the class described, having a can-head-feeding device, a can-head-receiving plate, and feeding device comprising a revolving disk upon which the can-heads are placed, a stopping and releasing device for holding the can-head temporarily stationary while the disk revolves, and a pushing-head for pushing a released head into the said plate, the latter being provided with retaining devices for holding the can-heads in place, substantially as shown and described.

32. A machine of the class described, having a can-head-feeding mechanism, comprising a revolving disk on which the heads are placed, and an automatically-actuated lever having a pin normally projecting into

the path of the heads in the disk, to hold the heads temporarily stationary while the disk revolves, substantially as shown and described.

33. A machine of the class described, having a can-head-feeding mechanism, comprising a revolving disk on which the heads are placed, an automatically-actuated lever having a pin normally projecting into the path of the heads in the disk, to hold the heads temporarily stationary while the disk revolves, and means for imparting a swinging motion to the said lever, to release the heads and allow the same to travel with the disk, substantially as shown and described.

34. A machine of the class described, having a can-head-feeding mechanism, comprising a revolving disk on which the heads are placed, an automatically-actuated lever having a pin normally projecting into the path of the heads in the disk, to hold the heads temporarily stationary while the disk revolves, and means for imparting a swinging motion to the said lever, to release the heads and allow the same to travel with the disk, and a head over the said disk, to hold the heads from accidental displacement thereon, substantially as shown and described.

35. A machine of the class described having a can-body-receiving plate, a shaft carrying said plate and provided with a gear-wheel at its upper end, and a mechanism for imparting an intermittent rotary motion to the said plate, the said mechanism comprising a second shaft carrying a pin at its upper end in mesh with the gear-wheel on the plate-shaft, a detent-wheel carried on the lower end of said second shaft and having radial recesses in its under side and peripheral notches, a third shaft mounted to rotate and provided with an arm having a friction-roller for engagement with the said notches, means for rotating said third shaft, a disk having a segmental notch and rotating in unison with the said arm, the peripheral surface of the disk being adapted to mesh with the said detent-wheel notches, substantially as shown and described.

36. A machine of the class described, having a roller for crimping or compressing purposes, a lever on which the roller is journaled, a link connected at one end with the lever, a casing into which the other end of the link extends, a spring surrounding said link within the casing, a lever pivotedly connected with the casing, and a cam for swinging the lever, substantially as shown and described.

37. In a machine of the class described, a roller for crimping or compressing purposes, a lever on which the roller is journaled, a casing, a link pivotedly connected with said lever and extending into the casing, the link having a head arranged within the casing, a spring coiled around said link within the casing, a lever pivotedly connected with the casing, and means for swinging the latter lever, substantially as shown and described.

38. In a machine of the class described, having a roller for crimping or compressing purposes, a lever on which the roller is journaled, means for imparting a swinging motion to the said lever, a bearing for the fulcrum of the lever, the said bearing being adjustably mounted, and an arm on said bearing carrying a stop-rod for limiting the swinging motion of said lever, substantially as shown and described.

39. In a machine of the class described, a roller for crimping or compressing purposes, a lever on which the roller is journaled means for imparting a swinging motion to said lever, a vertically-disposed pin forming the fulcrum for said lever, a bearing in which said pin is adjustably held, means for adjusting said bearing, and means for limiting the swinging motion of the lever, as set forth.

40. A machine of the class described, comprising an intermittently-rotating plate having retaining means for holding the can-bodies and can-heads and for allowing the same to be revolved in the plates, the said retaining means comprising an open clamping-ring secured to the plate, and having a segmental recess formed in its upper part to receive the can-head, the said clamping-ring being provided with a groove in the lower portion at the inner face, and spring-pressed clamping means extending in the recess and groove to engage the head and body of the can, means for engaging the can body and head to revolve the same in said retaining means, and a crimping-roller for engagement with the can-flanges to crimp the same while the said head and body are being rotated, substantially as shown and described.

41. A machine of the class described, comprising an intermittently-rotating plate having peripheral notches, and retaining means for holding the can-bodies and can-heads in position in said notches, and for allowing the same to be revolved in the notches, the said retaining means comprising an open clamping-ring secured to the plate at each notch and having a segmental recess in its upper part to receive the can-head, and provided with a groove in the lower portion at the inner face, and spring-pressed clamping means in said ring for engaging the head and body of the can, means for engaging the can body and head to revolve the same in said retaining means, and a compression-roller for engaging and compressing the seam of the can, to render the latter air-tight, substantially as shown and described.

42. A machine of the class described, comprising a plate or carrier for carrying the assembled can-body and can-head, a feeding device for

automatically feeding the can-bodies successively to the said plate, means for intermittently rotating the plates, an ejecting device operating in unison with the feeding device to eject a finished can at a time from the plate while the latter is at rest, and means for actuating the ejecting device, substantially as shown and described.

43. A machine of the class described, comprising a plate or carrier for carrying the assembled can-body and can-head, a feeding device for successively feeding the can-bodies successively to the said plate, means for intermittently rotating the said plate, a crimping device for engagement with the flanges of the can body and head, an ejecting device operating in unison with the feeding device to eject a finished can at a time from the said plate while the latter is at rest, and means for moving the ejecting device, substantially as shown and described.

44. A machine of the class described, comprising a plate or carrier for carrying the assembled can-body and can-head, a shaft carrying said plate and mounted to rotate and also to move vertically in its bearings, a plurality of devices for successively engaging the can body and head to clamp and to rotate the same, a crimping-roller for engaging the flanges of the can body and head to crimp the said flanges, the said crimping-roller operating in conjunction with one of the said clamping and rotating devices, a compression-roller operating in conjunction with the other clamping and rotating device, to compress the seam previously formed by the said crimping-roller, means for imparting an up-and-down motion to the shaft carrying the plate and an ejecting device for ejecting the finished can from the said plate, substantially as shown and described.

45. A machine of the class described, comprising a plate for carrying the can bodies and heads thereon, a shaft carrying said plate, and mounted to rotate and also to move vertically in its bearings, means for revolving the can body and head in the plates, a crimping-roller for engaging the can-flanges and crimping the same while the body revolves, and means for imparting an up-and-down motion to the shaft carrying the plate, substantially as shown and described.

46. A machine of the class described, comprising a plate or carrier for carrying the assembled can-body and can-head, means for imparting an intermittent rotary motion to the plate, and means for locking the plate in position during the period of rest, the said means comprising a bell-crank lever fulcrumed on the frame of the machine one end of the bell-crank lever being provided with a leg adapted to engage a notch in the peripheral surface of the plate, a second lever fulcrumed on the machine-frame and connected at its lower end by a link with the bell-crank lever, and a shaft mounted to turn and provided with a disk having a cam-groove in its face engaged by the upper end of said second lever for revolving the latter, substantially as shown and described.

47. A machine of the class described, comprising a can-body-receiving plate having retaining devices for the can-bodies, and a feeding mechanism for automatically feeding the can-bodies successively to the said retaining device, the said feeding mechanism being provided with a conveyor-frame having an endless conveyor-belt for the can-bodies, a bracket fitted to slide on a vertically-disposed post supported on the machine-frame, and in which the lower end of the conveyor-frame is hung, means for adjusting the bracket up or down on the post to bring the top run of the conveyor-belt to a proper level relative to the height of the can-body and the position of the plate, devices for interrupting the forward movement of the can-bodies on the belt, and for releasing the can-bodies, and means for pushing the can-bodies into the retaining devices of the plate, substantially as shown and described.

48. A machine of the class described, comprising a can-body-receiving plate having retaining devices for the can-bodies, an endless conveyor-belt for the can-bodies, a table located adjacent to the conveyor-belt, a pusher-rod having a head for engaging and pushing the can-bodies successively from the conveyor-belt upon said table and a pusher-head for pushing the can-bodies from said table into the retaining devices of the plate, substantially as shown and described.

49. A machine of the class described, comprising a can-body-receiving plate having retaining devices for the can-bodies, means for intermittently rotating said plate, a conveying mechanism having an endless belt for carrying the can-bodies, levers normally in engagement with the can-bodies to interrupt their forward movement, a pusher-rod having a head for engaging the can-bodies successively to push them from the conveyor-belt, mechanism for actuating said pusher-rod, and a connection between said mechanism and the said levers whereby the said levers are moved out of engagement with the can-bodies so that the latter can move forward with the belt on which they rest, and a pushing-head for pushing the can-bodies into the retaining devices of the plate, after they have been pushed from the conveyor-belt, substantially as shown and described.

50. In a machine of the class described, a can-body-receiving plate having retaining devices for the can-bodies, means for intermittently rotating the said plate, a pusher-head for feeding the can-bodies successively to the said retaining device, a can-head-feeding device, a can-head-receiving plate for bringing a can-head over a can-body in the said can-body-receiving plate, substantially as shown and described.

body-receiving plates, a pusher-head for pushing the can-head successively from the can-head-feeding device onto the can-head-receiving plates, a guideway for conveying the can to one side of the machine, a pusher-head for pushing a finished can from the can-body-receiving plates, upon said guideway, and connections between the said pusher-heads whereby they are operated in unison, substantially as shown and described.

51. In a machine of the class described, a plurality of devices for successively engaging the assembled can body and head to clamp and to rotate the same, the said devices each comprising a revoluble spindle for engaging a can-head and a revoluble support for engaging the bottom of a can, the said supports having axial movement, means for rotating the said supports and spindles in unison while permitting of the axial movement of the supports, and means for imparting a reciprocating movement to the said supports, a crimping-roller operating in conjunction with one of the said clamping and rotating devices, and a compressing-roller operating in conjunction with the other clamping and rotating device, substantially as shown and described.

52. In a machine of the class described, a plurality of devices for successively engaging the assembled can body and head to clamp and to rotate the same, the said devices each comprising a revoluble spindle, and a revoluble support for engaging an assembled can body and head to rotate the same, the said supports each comprising a shaft mounted to turn and to slide, and a head on said support, a gear-wheel on each of said shafts and meshing with an intermediate gear-wheel of greater width than the gear-wheels on the shafts, so that the latter gear-wheels can move vertically with their shafts without moving out of mesh with the intermediate gear-wheel, means for imparting a sliding motion to the said supports, and means for rotating the intermediate gear-wheel, substantially as shown and described.

53. A machine of the class described, provided with a platen for carrying the can bodies and heads thereon and an ejecting device for moving the finished can from the platen, the said ejecting device comprising a slide mounted to move in a guideway on the frame of the machine, a post carried by said slide, a head on the upper end of the post and adapted to engage a finished can, and means for imparting a sliding motion to said slide, substantially as shown and described.

54. A machine of the class described, provided with a platen having retaining devices for the cans, means for intermittently rotating the platen, a pusher-head for feeding the cans into the retaining devices of the platen, means for crimping and compressing the flanges of the can body and head while in the retaining device, a pusher-head for ejecting the finished can from the platen, and means for operating said pusher-heads in unison, substantially as shown and described.

55. A machine of the class described, provided with a platen having retaining devices for the cans, means for rotating said platen intermittently, a mechanism for feeding the assembled can bodies and heads to the retaining device and having a pusher-head for pushing the cans into the retaining device, means for crimping and compressing the flanges of the can body and head while in the retaining device, a pusher-head for ejecting a finished can from the platen and operating in unison with the first-mentioned pusher-head, and means for locking the platen while in a state of rest, substantially as shown and described.

56. A machine of the class described, provided with a platen having retaining devices for the cans, means for rotating said platen intermittently, a feeding mechanism for the cans having a pusher-head for pushing the cans into the retaining devices of the platen, a pusher-head for ejecting the finished can from the platen when in a state of rest, a bell-crank lever connected with said pusher-heads to operate the same in unison, and means for actuating the said lever, substantially as shown and described.

57. A machine of the class described, comprising a platen for carrying the can bodies and heads thereon, devices for engaging and revolving a can body and head in the platen for crimping or compressing purposes, one of said devices engaging the top of the can-head and having a depending canular flange, adapted to enter a recess or depression in the can-head to form an abutment during the crimping or compressing operation and means for pushing the can-head out of engagement with said flange, substantially as shown and described.

58. A machine of the class described, comprising an intermittently-rotating and vertically-movable platen for carrying the can bodies and heads thereon, means for revolving the can body and head in the platen, the said means consisting of a revoluble support arranged to engage the bottom of the can, and a revoluble spindle for engaging the can-head, the said spindle having a flange adapted to enter a recess in the can-head to serve as an abutment during the crimping operation, means for raising and lowering the platen and a crimping-roller for engaging and crimping the can-flanges while the body revolves, substantially as shown and described.

59. A machine of the class described, comprising an intermittently-

rotating and vertically-movable platen for carrying the can bodies and heads thereon, and for allowing the same to be revolved in the platen, a revoluble support arranged to engage the bottom of the can, a revoluble spindle for engaging the can-head and having a flange adapted to enter a recess in the can-head to serve as an abutment during the compressing of the can, means for moving the said platen vertically and a compressing-roller for engaging and compressing the seam of the can, to render the latter air-tight, substantially as shown and described.

60. A machine of the class described, comprising an intermittently-rotating platen having retaining means for holding the can-bodies and can-heads and for allowing the same to be revolved in the platen, a plurality of devices for successively engaging the assembled can body and head to clamp and to rotate the same in the platen, the said devices each comprising a revoluble spindle for engaging the can-head and having a flange adapted to enter a recess in the top of the can-head to serve as an abutment, and a support for engaging the bottom of the can and mounted to turn and to slide, a gear-wheel on each of said supports and meshing with an intermediate gear-wheel, the gear-wheels being arranged to permit of the vertical movement of the supports without disengagement of said gear-wheels, means for rotating the intermediate gear-wheel, means for imparting a sliding motion to the supports, a crimping-roller for the can-flanges operating in conjunction with one of the said clamping and rotating devices, and a compressing-roller for compressing the seam, and operating in conjunction with the other clamping and rotating device, substantially as shown and described.

61. A machine of the class described, comprising a can-body-receiving platen, having retaining means for holding a can-body, and for allowing the can-body to be turned in the platen, a revoluble support, a revoluble spindle in alignment with the support and arranged to engage a can body and head at the bottom and top and revolve the same, the said revoluble spindle having a depending flange adapted to enter a recess in the can, and serving as an abutment during the crimping operation, a crimping-roller for engagement with the flanges of the can-body and head, and a rod held in reciprocity in the said spindle to press the said can-head out of engagement with the flange of the spindle substantially as shown and described.

62. A machine of the class described, comprising a platen for carrying the can bodies and heads thereon, means for raising and lowering the platen, a device for clamping the can bodies and heads and for revolving the same, the said device when raised carrying the can bodies and heads into position to be clamped by said device, and when lowered exposing the flanges of the can body and head for crimping purposes, a crimping-roller having its peripheral surface formed with an angular groove for engaging the can-flanges and crimping the same while the body revolves, and an abutment forming a part of the clamping and revolving device, and acting in conjunction with the crimping-roller, substantially as shown and described.

63. A machine of the class described, comprising a platen for carrying the can bodies and heads thereon, means for raising and lowering the platen, a device for clamping the can bodies and heads after the platen is raised and for revolving the same, the said platen when lowered or in its normal position exposing the flanges of the can body and head for compressing purposes, a compressing-roller having a straight peripheral face for engaging and compressing the seam of the can, and an abutment forming a part of the said clamping and revolving device and acting in conjunction with the compressing-roller, substantially as shown and described.

64. A machine of the class described, comprising an intermittently-rotatable and vertically-movable can-body-receiving platen provided with means for the flanges of the can body and head, a revoluble spindle held against axial movement and provided with a head at its lower end and having a flange adapted to enter a groove in the can-head when the platen is raised, a revoluble and vertically-movable support for the bottom of the can to hold the can in position against the spindle, means for revolving said support and spindle, a roller adapted to engage the can-flanges when the platen recedes, and means for pushing the can from the flange of the spindle and into the can in the platen when the support recedes, substantially as shown and described.

65. A machine of the class described, comprising an intermittently-rotatable and vertically-movable can-body-receiving platen, having notches in its periphery and a clamping device for holding a can-body in a notch and for allowing the said can-body to be turned in the notch, the said clamping device having a recess forming a seat for the flanges of the can body and head, means for imparting a vertical reciprocating motion to the platen in an axial direction, a revoluble support, a revoluble spindle in alignment with the support and both in alignment with a platen-notch to engage the can body and head at the bottom and top and revolve the same, the said spindle being provided with a head having a depending flange arranged to enter a recess in the top of the can-head when the platen is raised, to serve as an abutment, means for rotating the support

and spindle in unison a roller for engagement with the flange of the can body and head after the platen is lowered and means for moving the can-head out of engagement with the flange of the spindle substantially as shown and described.

66. In a machine of the class described, a platen having a seat for the can-flanges, a device for rotating the assembled can body and head in the platen, and comprising a revoluble support having vertical movement, a revoluble spindle in alignment with the support and held against vertical movement, the said spindle being provided with means for engaging the top of the can-head to form an abutment during the crimping operation, and means for moving the can-head out of engagement with the spindle on the receding of the support, and into the seat in the platen, substantially as shown and described.

67. In a machine of the class described, a platen, a device for rotating the assembled can body and head in the platen, and comprising a revoluble support having axial movement, a revoluble spindle in alignment with the said support and held against axial movement, the said spindle being provided with a depending flange for engaging a recess in the top of the can-head, means for rotating the support and spindle, and a rod slidable in the said spindle and adapted to engage the can-head to move the latter out of engagement with the flange of the spindle and into a seat in the platen on the receding of the support, substantially as shown and described.

68. A machine of the class described, comprising an intermittently-revolving can-body-receiving platen, having a clamping-ring for retaining and holding the body and allowing the same to be revolved in the clamping-ring, the said ring having a recess in its upper portion forming a seat for the flange of the can-body, a can-head-receiving platen having intermittent motion in unison with the said can-body-receiving platen and adapted to engage the can-head, to bring a can-head over a can-body, and a reciprocating plunger for engaging the can-head and pressing the same out of the can-head-receiving platen onto the end of the can-body, the recess in the clamping-ring receiving the flange of the can-head and centering the can-head when the latter is pressed out of the platen, substantially as shown and described.

69. A machine of the class described, comprising a can-body-receiving platen or carrier, having retaining devices for the can-bodies, means for feeding the can-bodies successively to the retaining device of the platen, means for intermittently rotating the platen, a can-head-receiving platen rotating in unison with the can-body-receiving platen, and arranged to bring a can-head over a can-body, mechanism for feeding the can-heads to said can-head-receiving platen, a reciprocating plunger for pressing a can-head out of the can-head-receiving platen onto the end of the can-body, means for revolving the can body and head in said can-body-receiving platen, and means for crimping and compressing the flanges of the can body and head, substantially as shown and described.

70. A machine of the class described, comprising an intermittently-rotatable platen or carrier for carrying the assembled can-body and can-head, the said platen having a limited vertical movement, means for rotating the platen intermittently, a plurality of devices for successively engaging the can body and head to clamp and rotate the same, a crimping device for engaging the flanges of the can body and head to crimp the said flanges, the crimping device operating in conjunction with one of the said clamping and rotating devices, a compressing device operating in conjunction with the other clamping and rotating device to compress the seam previously formed by the said crimping device, mechanism for imparting a limited vertical movement to the platen, and means for actuating said mechanism, the said clamping and compressing devices being controlled from the said means, substantially as shown and described.

71. A machine of the class described, comprising a platen for carrying the can bodies and heads, means for imparting motion to the platen in an axial direction, means for clamping the can bodies and heads, when the platen is moved in one direction, and for revolving the same, the platen when moved in the opposite direction exposing the flanges for crimping or compressing purposes, substantially as shown and described.

698,703. **IMPROVEMENTS IN COLLING MACHINES.** ARMA C. GUNTER, Des Moines, Iowa. Filed Oct. 2, 1898. Serial No. 25,165. (No model.)

Claim.—1. In a coin-controlled machine, a frame pivoted at its lower end and provided with parallel sides at its top and coinciding vertical slots in the parallel sides of its top for receiving and retaining a coin, a spring-actuated pin mounted in horizontal position to engage a coin, placed in said slot, a pawl pivoted above the top of the pivoted frame for engaging and removing the coin from the said slot in the pivoted frame as the frame and pin resume their normal positions, a chamber for merchandise above the pivoted frame and pivoted pawl, a slidable bottom for said chamber, means for connecting the slidable bottom with said pivoted frame and means for connecting the pivoted frame with a rotatable card-carrier located above the said chamber for merchandise, arranged and combined to operate in the manner set forth for the purpose stated.

frame, arranged and combined to operate in the manner set forth for the purpose stated.

2. In a coin-controlled machine, a frame pivoted at its lower end and provided with parallel sides at its top and coinciding vertical slots in the parallel sides of its top for receiving and retaining a coin, a spring-actuated pin mounted in horizontal position to engage a coin, placed in said slot, a pawl pivoted above the top of the pivoted frame for engaging and removing the coin from the said slot in the pivoted frame as the frame and pin resume their normal positions, a chamber for merchandise above the pivoted frame and pivoted pawl, a slidable bottom for said chamber, means for connecting the slidable bottom with said pivoted frame and means for connecting the pivoted frame with a rotatable card-carrier located above the said chamber for merchandise, arranged and combined to operate in the manner set forth for the purpose stated.

3. In a coin-controlled machine for advertising and selling merchandise, a case having a slot to admit a coin, a frame having a slot in its top to receive a coin pivoted in the case, a spring-actuated pin to engage a coin in the slot of said pivoted frame, a chamber for articles of merchandise above the said slot in the case, a slidable bottom in the chamber, a lever connected with the slidable bottom at its top end, a coiled spring connected with the said pivoted frame and the lever and means for conveying hand-pressure to a coin in the top of said pivoted frame, a pawl pivoted to the case for removing the coin from the frame having a slot in its top to receive a coin, a rotatable card-carrier mounted above the chamber for merchandise, a ratchet-wheel on the axle of the card-carrier, a lever having a pawl at its top to engage the ratchet-wheel and a link at its bottom connecting it with the lever that is connected with the sliding bottom, all arranged and combined to be jointly and simultaneously operated in the manner set forth for the purpose stated, by pressure upon the coin.

4. A machine for advertising and selling merchandise comprising a case having a forward extension at its front and lower portion, a chamber for merchandise inside of its front wall and above the forward extension, a slidable bottom in said chamber, a spring-actuated frame pivoted in the forward extension, a slot in the top of the extension to admit and direct a coin into a coinciding slot in the top of said pivoted frame, a lever pivoted in the bottom of the case and connected with the slidable bottom of the chamber, a spring-actuated pin mounted in the front of the forward extension of the case to engage a coin in the top of said pivoted frame, a pawl pivoted to the top of said extension to pull the coin from the slot in the top of said pivoted frame, a rotatable card-holder mounted in the top of the case, a ratchet-wheel on the shaft of the card-holder, a lever fulcrumed to the inside of the case and provided with a pawl at its top to engage the ratchet-wheel and connected with the lever that is attached to the pivoted frame that has a slot in its top for holding a coin, a window in front of the case in alignment with the card-holder, all arranged and combined to simultaneously operate the slidable bottom of the chamber for merchandise, and the rotatable card-holder for advertising the merchandise by pressure upon a coin placed in the machine and transmitted to said slidable bottom and said rotatable card-holder by said plurality of levers.

698,708. **FEEDING-MECHANISM.** GEORGE WILLIAM FRIEDLAND, Phila. Pa. Filed May 21, 1898. Serial No. 25,166. (No model.)

Claim.—1. In combination with a main valve controlling the main

passage, said valve being normally closed by the pressure, a double-acting balanced valve controlling the inlet and outlet from the pressure-chamber above the main valve, a spring for exerting a constant pressure in the balanced valve and means for automatically actuating said valve against the pressure of the spring / on the decrease of pressure to allow the main valve to open, substantially as described.

2. In combination with a main valve controlling the main passage normally closed by the pressure, a valve controlling the inlet and exit of pressure, a spring set to operate at a predetermined pressure to cause the opening of the main valve, and manually-operating means adapted to be actuated to effect the temporary closing of the main valve without interfering with the predetermined tension of the spring, substantially as described.

3. In combination with a main valve controlling the main passage normally closed by the pressure, a balanced double-acting valve under spring tension controlling the inlet and exit of pressure to said main valve, a spring set at a certain tension for causing the actuation of said controlling-valve, to close the same and to permit the opening of the main valve at a predetermined pressure on the low-pressure side and manually-operated means for effecting the temporary closing of the main valve through the action of the controlling-valve without interfering with the tension of the main spring, substantially as described.

698,704. METHOD OF MAKING HYDROCHLORIC ACID. EDWARD HART, Boston, Pa., assignor to General Chemical Company, New York, N. Y., a Corporation of New York. Filed Nov. 5, 1901. Serial No. 51,171. (No specimens.)

Claim.—1. The herein-described process of manufacturing hydrochloric acid, which consists in heating sodium-pyrosulphate and sodium chloride in the presence of water.

2. The herein-described process of producing hydrochloric acid which consists in causing to react upon each other at a temperature below red heat, sodium pyrosulphate, sodium chloride, and water in substantially the proportion of two equivalents of sodium chloride, one equivalent of water and one equivalent of sodium pyrosulphate.

3. The herein-described improvement in the manufacture of hydrochloric acid which consists in subjecting a mixture of sodium pyrosulphate, sodium chloride and water to a temperature increasing gradually from one portion of the mixture to another, then coming the gas liberated to pass over the nearly-finished salt cake which results from the reaction together with the hydrochloric acid.

4. The herein-described improvement in the manufacture of hydrochloric acid which consists in heating a mixture of sodium chloride and sodium pyrosulphate, and continuing to heat the mixture to a temperature below red heat in the presence of water or steam, to cause the production of hydrochloric acid and salt cake or sodium sulfate.

698,705. TONGUING-AND-GROOVING MACHINE. HENRY A. BELL, Wilton, N. H. Filed Nov. 1, 1901. Serial No. 50,790. (No model.)

Claim.—1. In a machine of the character specified, a work-supporting table, a cutter-head, a shaft therefor, a vertically-movable support for said shaft and cutter-head, whereby the cutter-head may be adjusted vertically, and a rider connected with the shaft-support and arranged to be supported by the upper surface of a board on said table, whereby the height of the cutter-head is determined by the upper surface of the board.

2. In a machine of the character specified, a work-supporting table having a fixed edge guide, a swinging frame pivoted below the table, a cutter-head having a shaft journaled in bearings on the swinging end of the frame and movable toward and from the said guide, said shaft being vertically movable, a rider arranged to bear on the top surface of a board, and connections between the rider and shaft, whereby the height of the cutter-head is determined by the upper surface of the board.

3. A machine of the character specified, comprising a work-supporting table having a fixed edge guide, two cutter-heads, a horizontally-movable support for the bearings of one cutter-head yieldingly pressed toward said guide, vertically-movable supports for the shafts of the two cutter-heads, riders arranged to bear on the top surface of a board, and connections between said riders and the shaft-supports, whereby the height of the cutter-heads is determined by the upper surface of the board.

4. A machine of the character specified, comprising a work-supporting table having a fixed edge guide, a vertically-movable bearing-cutter held against lateral movement and located over said table, a vertically and horizontally movable cutter located over the table and movable toward and from the guide, and a proportional adjusting device actuated by the width of a board to adjust the horizontally-movable cutter.

5. A machine of the character specified, comprising a work-supporting table having a fixed edge guide, two pivoted frames located over the table and movable toward and from the same, one frame being horizontally movable and the other confined against horizontal movement, a proportional adjusting-lever pivoted at one end to the table and having at the other end a board-engaging shoulder, the lever being engaged at an intermediate point with the horizontally-movable frame.

698,706. WRINGER. EDGAR DOWLEY, Seattle, Wash. Filed July 1, 1901. Serial No. 50,908. (No model.)

Claim.—1. In a wringer of the nature indicated, a shaft having a jaw on one end and a crowing on one side edge adjacent thereto, having a curved surface, a movable L-shaped jaw with the stem disposed on said crowing and a yoke pivoted to the shaft on a line radial said surface at comparatively short radius, embracing said stem and adapted to swing and clamp the same to the crowing, and means for yieldingly holding the fulcrum of the yoke in its adjusted position.

2. In a wringer of the nature indicated, a shaft having a jaw on one end and a crowing on one side edge adjacent thereto, a transversely-disposed T-shaped die with the head parallel said surface, a movable L-shaped jaw with the stem disposed on said crowing, a yoke adjustably pivoted to said die, embracing said stem and adapted to swing and clamp the same to the crowing and means to yieldingly secure the pivot of said yoke in adjusted position in the die, and lifting-springs between said shaft and die.

3. In a wringer of the nature indicated, a shaft having a jaw on one end and a crowing on one side edge adjacent thereto and a transversely-disposed T-shaped die with the head parallel said surface, a movable L-shaped jaw with the stem disposed on said crowing, a yoke adjustably pivoted to said die embracing said stem and adapted to swing and clamp the same to the crowing and a U-shaped spring disposed in the crowing and means for yieldingly holding the fulcrum of the yoke in its adjusted position.

4. In a wringer of the nature indicated, a shaft having a jaw on one end and a crowing on one side edge adjacent thereto and a transversely-disposed T-shaped die with the head parallel said surface, a movable L-shaped jaw with the stem disposed on said crowing, a yoke adjustably pivoted to said die embracing said stem and adapted to swing and clamp the same to the crowing and a U-shaped spring disposed in the crowing and means for yieldingly holding the fulcrum of the yoke in its adjusted position.

5. In a wringer of the nature indicated, a shaft having a jaw on one end and a crowing on one side edge adjacent thereto having a curved surface and a transversely-disposed T-shaped die with the head substantially parallel said surface, a movable L-shaped jaw having teeth formed in the stem adapted to normally interlock with the teeth on said crowing, a yoke adjustably pivoted in said die embracing said stem and adapted to swing and hold the same to the crowing and a U-shaped spring disposed in the head of said die with one stem yieldingly holding the pivot of said yoke normally in the stem of the die.

6. In a wringer of the nature indicated, a shaft having a jaw on one end and a crowing on one side edge adjacent thereto having a curved surface and a transversely-disposed T-shaped die with the head substantially parallel said surface, a movable L-shaped jaw having teeth formed in the stem adapted to normally interlock with the teeth on said crowing, a yoke adjustably pivoted in said die embracing said stem and adapted to swing and hold the same to the crowing and a U-shaped spring disposed in the head of said die with one stem yieldingly holding the pivot of said yoke normally in the stem of said die.

7. In a wringer of the nature indicated, a shaft having a jaw on one end and a crowing on one side edge adjacent thereto having a curved surface and a transversely-disposed T-shaped die with the head substantially parallel said surface, a movable L-shaped jaw having teeth formed in the stem adapted to normally interlock with the teeth on said crowing, a yoke adjustably pivoted in said die embracing said stem and adapted to swing and hold the same to the crowing and a U-shaped spring disposed in the head of said die with one stem yieldingly holding the pivot of said yoke normally in the stem of said die.

8. In a wringer of the nature indicated, a shaft having a jaw on one end and a crowing on one side edge adjacent thereto having a curved surface and a transversely-disposed T-shaped die with the head substantially parallel said surface, a movable L-shaped jaw having teeth formed in the stem adapted to normally interlock with the teeth on said crowing, a yoke adjustably pivoted in said die embracing said stem and adapted to swing and hold the same to the crowing and a U-shaped spring disposed in the head of said die with one stem yieldingly holding the pivot of said yoke normally in the stem of said die and a spring at one end of the crowing connected to the shaft and pressing upon said stem, and adapted to raise and yieldingly support said movable jaw when the yoke is adjusted outwardly.

698,707. METHOD OF MAKING HOLLOW BALLS. ALLEN JENNISON, Ottumwa, Iowa. Filed Sept. 25, 1900. Serial No. 75,504. (No model.)

Claim.—1. The process of making hollow metal bearing-balls, which consists in forming a cup, closing the edge of the cup to form a sphere, and subjecting the same to increasing rolling pressure on its various axes, thereby truing and condensing the surface of said sphere.

2. The process of making hollow metal bearing-balls, which consists in forming a cup having an irregular edge, closing the edge of the cup to form a sphere, and subjecting the same to increasing rolling pressure on its various axes, thereby truing and condensing the surface of said sphere.

3. The method of making a hollow metal ball consisting of shaping a piece of metal of suitable size into a cup, then closing the edge of the cup to form a hollow sphere, and finally subjecting said hollow sphere to pressure on its various axes.

4. The process of making hollow metal bearing-balls, which consists of shaping a metal blank into a cup, closing the edge of the cup to form a sphere and subjecting the same to a gradually-increasing rolling pressure on its various axes as set forth.

5. The process of making hollow metal bearing-balls, which consists of shaping a sheet-metal blank into a cup, closing the edge of the cup to form a sphere, and subjecting the same to a gradually-increasing rolling pressure on its various axes.

6. The process of making hollow metal bearing-balls, which consists of shaping a metal blank into a cup having an irregular edge, closing the edge of the cup to form a sphere, and subjecting the same to a gradually-increasing rolling pressure on its various axes.

7. The process of making hollow metal bearing-balls, which consists of shaping a sheet-metal blank into a cup having an irregular edge, closing the edge of the cup to form a sphere, and subjecting the same to a gradually-increasing rolling pressure on its various axes.

8. The process of making hollow metal bearing-balls, which consists of shaping a metal blank into a cup, approximating the edge of the cup, to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition as set forth.

9. The process of making hollow metal bearing-balls, which consists of shaping a sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of said sphere into a hardened, polished condition.

10. The process of making hollow metal bearing-balls, which consists of shaping a metal blank into a cup having an irregular edge, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of said sphere into a hardened, polished condition.

11. The process of making hollow metal bearing-balls, which consists of shaping a sheet-metal blank into a cup having an irregular edge, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of said sphere into a hardened, polished condition.

12. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

13. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

14. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

15. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

16. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

17. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

18. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

19. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

20. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

21. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

22. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

23. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

24. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

25. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

26. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

27. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

28. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

29. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

30. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

31. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

32. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

33. The process of making hollow metal bearing-balls, which consists of shaping a square sheet-metal blank into a cup, approximating the edge of the cup to form a sphere, and subjecting the sphere repeatedly to gradually-increasing rolling pressure on its various axes, thereby pressing, swelling and condensing the surface of the same into a hardened, polished condition.

698,708. FIRE-POT FOR STOVE. WILLIAM J. KEMP, Detroit, Mich., assignor to the Michigan Stove Company, Detroit, Mich. Filed Feb. 28, 1901. Serial No. 45,772. (No model.)

Claim.—1. In a fire-pot, the combination of an upper and lower section provided with cooperating flanges extending outwardly from the walls thereof, said flanges formed to space the walls of the upper section from those of the lower section and to provide between them and the mid walls an annular air-space leading into the fire-pot, the walls of the lower section being bent outward to form a groove extending from the upper to the lower edge of said lower section and a plate adapted to form a continuation of the wall of said lower section and to cover said groove so as to form an inclined air-passage opening at its upper end into said air-space and opening at its lower end to the air below the fire-pot.

2. In a fire-pot, the combination of an upper and lower section provided with cooperating flanges extending outwardly from the walls thereof, said flanges formed to space the walls of the upper section from those of the lower section and to provide between them and the mid walls an annular air-space leading into the fire-pot, the walls of the lower section being bent outward to form a groove extending from the upper to the lower edge of said lower section and a plate adapted to form a continuation of the wall of said lower section and to cover said groove so as to form an inclined air-passage opening at its upper end into said air-space and opening at its lower end to the air below the fire-pot, the outwardly-extending flange of the upper section being provided with a dome forming an enlargement of said annular air-space above said air-passage.

698,709. RECIPROCATING KEY-WEATHER ATTACHMENT FOR DRILL. HOWARD W. KELLEY, Trenton, N. J. Filed Aug. 21, 1901. Serial No. 72,784. (No model.)

Claim.—1. A reciprocating key-weather attachment for drills, comprising a hanger adapted to be removably attached to a reciprocable part of a hand drill, a tool-holder carried by said hanger, a transverse slot in said tool-holder, a cutting-tool or chisel mounted in said slot adapted to project from said tool-holder for cutting a key-way, and means also carried by said hanger for advancing said cutting-tool, said means including a step-by-step mechanism actuated by the reciprocation of the hanger relatively to a stationary part of the drill.

2. A reciprocating key-weather attachment for drills, comprising a hanger adapted to be removably attached to the reciprocable drill-shaft support, a hollow tool-holder secured rigidly to the outer end of said hanger and provided at its free end with a transverse slot, a cutting-tool movable in said slot and provided with an inclined upper surface, a threaded plunger rotatable in said holder and cooperating with said inclined surface of the cutting-tool for feeding the latter, a ratchet mechanism also mounted on said hanger for rotating said plunger, and means carried by said hanger for drawing into contact with a stationary part of the drill upon each reciprocation of the hanger for operating said ratchet.

3. A reciprocating key-weather attachment for drills, comprising a hanger adapted to be removably attached to the reciprocable drill-shaft support, said hanger on its lower end having a hollow threaded bore, a cap mounted thereon and having a threaded opening in line with said hollow bore, a tool-holder mounted at one end in said threaded opening and at its other end carrying a radially-moving cutting-tool or chisel, a rotary plunger fitting within said tool-holder, said plunger and said tool-holder

having cooperating screw-threads for feeding the plunger, and said tool having an inclined feeding-surface for cooperating with the plunger, a ratchet-drove mounted in said hollow bore above said tool-holder, the latter being connected to rotate with said drive and mechanism for operating said ratchet-drove step by step as the drill-shaft support is reciprocated.

698,710. AIR PUMP. GEORGE W. KILLGUS, Hartford, Conn. Filed Feb. 12, 1901. Serial No. 47,108. (No model.)

Claim.—1. In an air-pump, the two cylinders of unequal diameter, the smaller one being mounted end to end upon the other and at one side of its center, a piston in each cylinder having a hollow rigid connection with that in the other whereby the cylinders may communicate, and mechanism for moving the pistons mounted upon the side of the smaller cylinder and connected through the end of the larger cylinder to its piston.

2. In an air-pump, two cylinders mounted endwise one upon the other, two rigidly-connected pistons, one in each cylinder, an arm connected to a cylinder on its exterior to rotate about its support thereon, a rod pivotedly connected to the piston of the other cylinder and to said arm, and an extension fixed to the arm for rotating it and the piston end of the rod about the exterior pivot-support of the arm.

3. In an air-pump, two cylinders mounted endwise one upon the other, two rigidly-connected pistons one in each cylinder, an arm connected to the exterior of a cylinder to rotate about its support thereon, a rod pivotedly connected to the piston of the other cylinder and to said arm, a piston-extending arm extension to rotate the arm and rod about the pivot-support of the arm, said arm, arm extension and rod being adapted to be held adjacent the cylinders and lengthwise thereof when at rest.

4. In an air-pump, two cylinders mounted endwise one upon the other, two rigidly-connected pistons one in each cylinder, an arm connected to the exterior of a cylinder to rotate about its support thereon, a rod pivotedly connected to the piston of the other cylinder and to said arm, a piston-extending arm extension to rotate the arm and rod about the pivot-support of the arm, said arm, arm extension and rod being adapted to be held adjacent the cylinders and lengthwise thereof, and said arm extension being detachable.

5. The pump comprising two lengthwise-connected cylinders of unequal size, the smaller being mounted concentrically on the larger, a piston in each cylinder, a port tube connecting said pistons, and a device for simultaneously operating said pistons comprising a member passing through the end of the larger cylinder adjacent the connected end of the smaller and connected to the piston of the larger cylinder.

6. The pump comprising two lengthwise-connected cylinders of unequal size, the smaller being mounted concentrically on the larger, a piston in each cylinder, a port tube connecting said pistons, and a device for simultaneously operating said pistons comprising a member passing through the end of the larger cylinder adjacent the connected end of the smaller and connected to the piston of the larger cylinder, said tube having a check-valve.

7. The pump comprising two lengthwise-communicating cylinders of unequal size, the smaller being mounted concentrically on the larger, pistons, one in each cylinder, and means for operating the pistons comprising a member passing through the end of the larger cylinder.

698,711. STERILIZING APPARATUS. GEORGE W. KILLGUS, Hartford, Conn. Filed Apr. 18, 1901. Serial No. 55,478. (No model.)

Claim.—1. In an apparatus for sterilizing, a sterilizing-chamber having walls including a steam and water chamber, a water-holder communicating with the latter chamber, tubes whereby said chamber and holder communicate, a heater for heating water in the holder and generating steam.

2. In an apparatus for sterilizing, a sterilizing-chamber surrounded by a steam-chamber, a condenser whereby the latter chamber may communicate with the former, and a cock for opening and closing the condenser whereby said condenser may be put in communication with the atmosphere, and a deflecting-cap directed over the outlet of the condenser into the sterilizing-chamber.

3. In a sterilizing apparatus, a sterilizing-chamber induced by a shell, an outer shell surrounding said chamber and providing a steam-jacket therefor, and a heat flanged ring closing the space between the shells and extended inwardly beyond the inner shell to provide for the attachment of a door by parts bearing on opposite sides of said inward extension and within the inner shell, said ring having its outer part bent parallel with and contiguous the outer shell and having its flange parallel with and contiguous the inner shell and both shells fixed to the ring.

4. In a sterilizing apparatus, a sterilizing-chamber induced by a shell, an outer shell surrounding said chamber and providing a steam-jacket therefor, and a heat flanged ring closing the space between the shells and extended inwardly beyond the inner shell to provide for the attachment of a door by parts bearing on opposite sides of said inward extension and within the inner shell, said ring having its outer part bent parallel with and contiguous the outer shell and having its flange parallel with and contiguous the inner shell and both shells fixed to the ring, said extension having a suitable circular projection to engage the door near its periphery.

698,712. WEATHER-STRIP. HENRY E. KIMM, Detroit, Mich., assignor to the Chamberlain Metal Weather Strip Co., Detroit, Mich. Filed Oct. 28, 1901. Serial No. 52,175. (No model.)

Claim.—1. The combination of the upper and lower meeting-ends of meeting casings, a U-shaped strip attached to the lower edge of the upper casing, a flanged strip attached to the lower and opposite edge of the upper rail of the lower casing and adapted to be inserted in the U-groove formed in the strip attached to the lower rail of the upper casing on closing the casing, the outer and projecting flange of the U-shaped strip attached to the upper rail being adapted to meet the wood of the outer side of the upper rail of the lower casing behind the metal strip attached thereto, substantially as described.

2. The combination of the upper and lower meeting-ends of meeting casings, a recess cut in the vertical surface of the lower edge of the lower rail of the upper casing, a U-shaped strip of metal attached in said recess to said lower rail of the upper casing and having a shorter lip projecting outwardly and upwardly therefrom, a rabbet or groove cut in the vertical face and lower edge of the upper rail of the lower casing, a flanged strip of metal fixedly attached in said groove and adapted to be inserted in the angle formed in the strip of metal attached to the opposite casing, substantially as described.

698,713. APPLIANCE FOR ASSISTING THE HEARING. PAUL A. KLAUS, Melbourne, Victoria, Australia. Filed Oct. 2, 1901. Serial No. 77,817. (No model.)

Claim.—1. An appliance comprising handle, arm pivoted thereto, enlarged shells or lobes at the extremities of the arm formed to fit upon the ears of wearer and means for doubling back the arm near the shells substantially as and for the purposes described.

2. An appliance comprising handle, arm pivoted thereto and formed in two portions hinged together and having grooves in and above it with screw-pins for making the rods rigid or releasing same to double back, enlarged shells or lobes, at the extremities of the arm, of basin form with recessed-out portion to fit the ears of wearer and with turned-over edge at the recessed portion substantially as and for the purposes described.

3. An appliance comprising arms pivoted together at the center and carrying at the extremities enlarged shells or lobes formed with recessed-out portion to fit upon the ears of wearer and having light spring connection at either side of the recess and means comprising hooked bar, for additionally holding the appliance in position substantially as and for the purposes described.

698,714. BOTTLE-LOCK. WILHELM KLAS, Magdeburg, Germany. Filed Nov. 12, 1901. Serial No. 52,011. (No model.)

Claim.—The combination with a frame of a bicycle, a brake-rod provided with a brake, a ring or collar secured to said brake-rod, a lock-casing clamped to the frame of a fork pivoted to said lock-casing adapted to embrace the brake-rod and engage the collar thereon, spring-tensioning means within said casing adapted to engage the shoulder on the rear end of the fork and hold the fork in locked position and the engage the rear end of said fork and hold it in unlocked position, substantially as set forth.

698,715. LOOS-EXTERMINATOR. JOHN KIMM, Canyon, Tex. Filed July 28, 1901. Serial No. 55,597. (No model.)

Claim.—An implement for exterminating locs and extracting plants by the root, the same consisting of a straight flat blade having a slot at its lower end, and having the slot portion sharpened to an edge, a flat chisel extended from the blade at an inclination and fastened to a side of the handle, and transversely-angled extensions projected laterally from the chisel at a point between its ends to form foot-rests and a fulcrum for the implement to turn upon, said chisel, blade and chisel being integrally formed, substantially as set forth.

698,716. BEE-BOTTLE AND LOCK-CHAL BOTTLE. WILLIAM T. KIMMEL, Brooklyn, N. Y. Filed Mar. 2, 1901. Serial No. 52,011. (No model.)

Claim.—1. In a non-refillable and lock-closing bottle, the combination of a bottle-neck, X, having a ledge or shoulder, X', formed thereon, with the separate pyramidal valve-cap, 1, seated in the lower part of

mid bulge or chamber, X, the external sealing-flange, 2, and packing, 3, having radial, oblique orifices or passages, 4, the conical valve-tube, 5, inserted at the bottom end and housed within the separate pyramidal valve-socket, 1, a float-valve, 6, having a pendant tapered guiding-stem, 6, and disk head, 7, and resting over it the hollow ball-weight, 8, partially filled with mercury, placed within the pyramidal valve-socket, 1, substantially as shown and specified.

2. In a non-refillable and leak-proof bottle, the combination of a bottle-neck, X, having a bulge or chamber, X', formed therein with the separate pyramidal valve-socket, 1, with all its mechanical parts within and the separate tubular throat-piece, 9, slid within the bottle-neck, X, and placed over the pyramidal socket, 1, making no contact between the two, said separated tubular throat-piece, 9, having the closed diaphragm, 10, and liquid and air orifices or passages, 11, the conical flange shoulder-ring, 11, and packing, 10, below the said flange shoulder-ring, to prevent the ingress of liquids into the conical space, 22, formed between the tubular throat-piece, 9, and bottle-neck, X, the corrugated flexible or elastic leak-proof ring disk, 14, encircling said tubular throat-piece and abutting against the flange shoulder-ring, 11, and housed within the diametrically-enlarged conical groove, 17, with its expanded, corrugated rim, by means of the blunted or split flange collar-cap, 15, having the flange, 16, and conical recess or depressed shoulder-flange, 20, the coupling-pin, 23, and the vertical longitudinal head-openings, 12 and 13, for the vertical longitudinal flange-heads, 12 and 13, to be housed in surrounding the tubular throat-piece below the reinforced top flange, 18, substantially as shown and specified.

3. In a non-refillable and leak-proof bottle, the combination of the tubular throat-piece, 9, surrounded with the compressing and retarding, flexible or elastic corrugated leak-proof ring disk, 14, permanently housed within the diametrically-enlarged conical groove, 17, when expanded, with the blunted collar-cap, 15, surrounding the tubular throat-piece below the reinforced top flange, 18, provided with coupling-pin, 23, holding the knotted loop ends, 25, of the tag, 24, concealed and effectively secure from displacement or removal, substantially as described.

4. In a non-refillable and leak-proof bottle, having in its neck, X, the bulge or chamber, X', in its base, the inserted separate non-refillable pyramidal valve-socket, 1, with all its mechanical parts held within inserted in its neck, X, the tubular throat-piece, 9, actuated by the flexible or elastic leak-proof ring disk, 14, housed and expanded within the diametrically-enlarged groove, and the reinforced top flange, in combination with the blunted or split collar-cap, 15, provided with the conical recess or depressed flange, 20, having the vertical longitudinal flange-openings, 12 and 13, housing the vertical longitudinal flange-heads, 12 and 13, the coupling-pin, 23, and the securely-looped tag or tablet, 24, held within, thereby not disturbing, removing or destroying any of the non-refillable and leak-proof integral parts of this device when uncorking or opening the bottle for the pouring out of the liquid, substantially as shown and described.

5. In a non-refillable and leak-proof bottle, the combination of a bottle-neck, X, having the diametrically-enlarged conical groove, 17, with the tubular throat-piece, 9, provided with a closed diaphragm, 10, and liquid and air orifices, 11, the shoulder-flange ring, 11, encircled with the compressing and retarding flexible or elastic corrugated leak-proof ring disk, 14, permanently housed within the said conical groove, 17, when expanded, substantially as specified and shown.

698,717. FARM-GATE. JOHN H. LAMBERT, Port Wayne, Ind., assignor of one-half to Thomas L. Lamson, Port Wayne, Ind. Filed Jan. 14, 1902. Serial No. 98,944. (No model.)

Claim.—1. The combination in a farm-gate of a pivoted hanger; a block pivotally mounted in the free end of the said hanger; a horizontal pivot-pin fixed in said block, and provided with a removable thumb-screw to permit the ready removal of the gate-body without displacing the said pivoted block or pivot-pin; and a gate-body slotted as described midway of its ends, and pivotally mounted on said pivot-pin, and adapted for both a vertical adjustment and a tilting movement thereon.

2. In a farm-gate a pivoted hanger-frame; means for adjusting the said hanger when out of plumb as described; an upright block pivotally mounted in the free end of said hanger; a horizontal pivot-pin for the gate-body arranged in the said block midway of its ends; and a gate-body having a vertical slot midway of its ends by means of which it is pivotally mounted on the said pin and is thereby adapted for both a vertical adjustment and a tilting movement thereon.

3. The combination in a gate of a pivoted hanger; a block pivotally mounted in the free end of said hanger; a horizontal pivot-pin for the gate-body passing through said block; a gate-body having a vertical slot midway of its ends, and adapted to receive the said pin, whereby the said gate is pivotally supported on the said pin and is adapted for both a vertical adjustment and a tilting movement thereon; and means for supporting the gate-body at the uppermost limit of its vertical adjustment.

698,718. HYDRA-COUP. WILLIAM C. LEAH, Seattle, Wash., assignor of one-half to John H. Leach, Seattle, Wash. Filed Oct. 22, 1902. Serial No. 28,504. (No model.)

Claim.—A device of the nature indicated, comprising a head having an integral chuck and a jaw with a longitudinally-convex face, a recess in the head and ribs longitudinally of the face of the jaw, a second jaw having its face formed like the first said jaw and having a circular lip fitting snugly in the said recess and shoulder abutting against the edge of the mouth thereof, a piston concentric with said lip and the recess, a clamp for each jaw-face consisting of a cast-steel body slidably fitting the said concave and grooved to receive the ribs and having screw-threads in the gripping-surfaces, a screw-clamp comprising an open rectangular frame embracing both jaws and hinged to the first said jaw and having a set-screw impinging the back of the second jaw.

698,719. MACHINE FOR CUTTING WOOD PILES. GEORGE E. LE CLAIR, Myra, Ohio, assignor to John W. Voelkening, Myra, Ohio. Filed Aug. 28, 1901. Serial No. 72,828. (No model.)

Claim.—1. In wood-floor-cutting machines, a gang of saws and a shaft with fixed bearings supporting the saws, in combination with a leg-supporting frame pivoted at its bottom in the main frame, and mechanism engaging said leg-supporting frame and adapted to move it back and forth, said mechanism comprising a yoke pivoted to said leg-supporting frame and a rotatable shaft in fixed bearings operatively engaging said yoke, substantially as described.

2. The main frame and the saws supported therein, in combination with the pivoted leg-frame and the spindle for the leg, a yoke pivoted on said leg-frame and an operating-shaft running through a cut fixed loosely in said frame, said shaft being rotatably supported at its ends, substantially as described.

3. The main frame and the set of saws, in combination with the pivoted leg-frame, a yoke pivoted on said leg-frame and a screw engaged in said yoke to carry the leg-frame toward and from the saws, power mechanism to rotate said screw and a clutch to engage and disengage said mechanism, substantially as described.

4. The main frame and the series of saws thereon, in combination with the pivoted leg-frame, a yoke pivoted on said frame about its middle and means connected therewith to adjust the leg-frame back and forth, leg-supporting spindles in the leg-frame above the main frame, power-driven mechanism connected with one of said spindles to rotate the leg and means to graduate the speed of said mechanism, substantially as described.

5. The pivoted leg-supporting frame and the yoke connected therewith, a screw-shaft operatively engaged in said frame to feed the leg, a clutch controlling the operation of said shaft, and means to disengage the clutch arranged to be actuated by said yoke, substantially as described.

6. In a wood-floor-cutting machine, a set of saws, a pivoted leg-supporting frame and a yoke connected therewith, in combination with a screw-shaft engaged in said yoke, power mechanism for rotating the shaft comprising a clutch applied on said shaft, push mechanism adapted to be engaged by said yoke and connected with said clutch to disengage the same, and a handle on said shaft to rotate the same for cutting the said leg-frame, substantially as described.

698,720. PUMP-BARRIER. JOHN H. LEACH, Seattle, Ind., assignor of one-half to George L. Leach, Seattle, Ind. Filed Jan. 14, 1902. Serial No. 98,945. (No model.)

Claim.—1. A pump-barrier having a pivoted arm projecting beyond the fulcrum thereof and adapted to be attached to a pump-rod or plunger, whereby the handle and pivoted arm may be oscillated independently of each other, and means to lock the arm to the handle to adapt the same to be operated thereby, substantially as described.

2. A pump-barrier having an arm slidably jointed thereto and adapted to be attached to a pump-rod or plunger, and a dog to connect the pump-handle and arm, and adapt the latter to be operated by the former, substantially as described.

3. The combination of a pump-barrier and an arm pivoted thereto, the one of said pivot and the fulcrum of the handle being coincident, the opposing ends of the handle and arm being adapted to abut against each other and means to lock the handle to the arm, substantially as described.

698,721. PUMP-ROD COUPLING. JOHN H. LEACH, Seattle, Ind., assignor of one-third to George L. Leach, Seattle, Ind. Filed Feb. 6, 1902. Serial No. 98,946. (No model.)

Claim.—1. In a pump-rod coupling, including a slide adapted to be connected to a plunger-rod, and a pump-rod, said slide and pump-rod having openings adapted to register with each other, a spring-pressed link-arm pivotally mounted on the slide, a coupling-pin pivotally connected to the link-arm and adapted to enter the slide and pump-rod openings when the same register, and an operating-lever, pivoted to the link-arm and bearing at one end against the slide, said link-arm having steps to limit the play of said lever, substantially as described.

2. In a pump-rod coupling, including a slide adapted to be connected to a plunger-rod and a pump-rod, said slide and pump-rod having pin-openings adapted to register with each other, a bearing-frame secured and adjustable on the slide, a spring-pressed link carried by said adjustable bearing-frame, a coupling-pin carried by the link and adapted to enter the slide and pump-rod openings when the same register with each other and means to operate said link and lock the same with the coupling-pin in engaged or disengaged position, substantially as described.

3. In a pump-rod coupling, including a slide adapted to be connected to a plunger-rod and a pump-rod, said slide and pump-rod having pin-openings adapted to register with each other, a frame secured and adjustable on the slide, a spring-pressed link carried by the frame, a coupling-pin connected to the link and adapted to enter the slide and pump-rod openings when the same register with each other, and an operating-lever pivoted to the link and bearing at one end against the slide, said link having steps to limit the play of said lever, substantially as described.

4. In a pump-rod coupling, including a slide adapted to be connected to a pump-rod and a plunger-rod, and having a pin-opening to register with an opening in the pump-rod, a link having a coupling-pin to enter said opening, means to lock said link with the pin in engaged or disengaged position, and a bearing for said link, said bearing being attached to and adjustable on the slide, substantially as described.

5. As a new article of manufacture, a bearing-frame having means whereby it may be attached to and adjusted on the slide of a pump-rod coupling, a link pivoted to and carried by said bearing-frame, a coupling-pin carried by said link, a spring coacting with said link of normally engage said coupling-pin with the opening of the slide and pump-rod, and an operating-lever pivoted to said link to bear against the slide and coact with the slide, link and spring to lock the link with its coupling-pin in engaged or disengaged position, substantially as described.

698,722. SHUTTLE-ROD OPERATOR. FRANK E. WHEELER, Philadelphia, and FRANK E. WHEELER, Dumbarton, N. Y. Filed Jan. 2, 1902. Serial No. 98,947. (No model.)

Claim.—1. In a shuttle-rod operator of the class described, the combination

with an inverted bell connected to gasometer and gasometer, a water-cistern for receiving acid, and means controlled by the position of the gasometer for automatically delivering acid into said bell, of means for receiving and expelling acid within said bell and for discharging the charge therefrom into acid cistern.

2. In an apparatus of the class described, the combination with an elongated acid-holder, a carbide-holder, a gas-generating chamber and a gasometer, of a water-cistern, having means for automatically maintaining a predetermined level of water therein, means controlled by said gasometer for automatically delivering acid into said gas-generating-chamber, and means for receiving and holding acid carbide within said chamber while being elided, and for discharging the residue into the cistern.

3. An apparatus of the class described, adapted for outdoor and subterranean installation, comprising in combination a cistern; a carbide-holder; a gas-generating chamber submerged in the water of the cistern; a gasometer connected therewith; means controlled by the gasometer for automatically feeding carbide into said chamber; and means for receiving and holding such carbide within said chamber and beneath the water-level while being elided, and for discharging the residue thereof into the cistern.

698,728. VERMIF-EXTERMINATOR. MELVIN J. HARTMAN and GEORGE E. ARNOLD, Edinboro, Pa. Filed Feb. 12, 1902. Serial No. 98,708. (No model.)

Claim.—1. The combination with a receptacle having a slit in one end thereof; of an elastic covering for said slit having a hand-receiving aperture therein.

2. The combination with a receptacle having a slit in one end; of a slide in said slit and having a slit therein, and an elastic covering for the slit in the slide, said covering having a hand-receiving aperture.

3. The combination with a receptacle having a slit in one end; of a slide mounted in said slit and having a slit therein, a flexible covering for the slit in the slide and having an aperture therein adjustable to the neck of a foot.

4. The combination with a receptacle having a slit in one end; of a reversible, slotted slide in said slit, and an elastic covering for the slit in the slide, said covering having a hand-receiving aperture.

5. The combination with a receptacle; of holding-strings adjustably

698,724. APPARATUS FOR DISTILLING WATER. EDWARD E. HURST, Boston, Mass., assignor, by mesne assignments, to the Portable Water Still Company, Boston, Mass., a Corporation of Maine. Filed Dec. 31, 1901. Serial No. 798,514. (No model.)

Claim.—1. An apparatus of the character specified, comprising an elongated vertical casing having means for applying a film of water to the outside thereof and outside of the casing being exposed to the atmosphere to permit evaporation of said film, said casing being partitioned to form a plurality of chambers one above another, a vertical perforated pipe in each of said chambers, means for applying steam to the lower perforated pipe, means whereby steam from the lower pipe that is not condensed in the lower chamber may pass into and through the upper perforated pipe into the upper chamber, means for permitting the escape of water of condensation from the upper chamber into the lower one, and means for drawing off water of condensation from the lower chamber.

2. In an apparatus of the character specified, the filter and means for applying steam thereto, the vertical casing divided into upper chamber *a* and lower chamber *b*, a connection between the filter and the lower chamber *b*, both of said chambers *a* and *b* being connected and each formed to insure the passage of steam through a body of water, the chamber *a* each having a vertical perforated pipe *c* within it, said chambers *a* being connected together and a connection being formed between the lower pipe *c* and the upper chamber *b*, means for applying water to the outside of the casing *a*, and means for permitting the escape of steam from the upper end of the upper chamber *a*.

698,725. COOLING-TIRE. ELMER T. MYERS, Colorado Springs, Colo. Filed July 15, 1901. Serial No. 98,541. (No model.)

Claim.—1. The combination with an outer porous vessel, a metallic receptacle of less diameter than said vessel mounted in the latter, and a lid or cover for the receptacle comprising a pan and a porous plate thereover, the latter having a tubular grip in communication therewith to serve as a water-filling means therefor.

2. The combination with an outer porous vessel, a metallic receptacle of less diameter than said vessel mounted in the latter, the bottom of the vessel being elevated above its support and the bottom of the receptacle being held above the bottom of the vessel, water being introduced

between the receptacle and vessel, a lid or cover for the receptacle comprising a water-pan and a porous plate removably attached thereto and having an annular tubular member rising therefrom to serve as a grip and means for supplying water to the pan, and means for supplying fresh air to the receptacle and cooling the air before entering the latter.

3. The combination of an outer porous vessel, a metallic receptacle of less diameter than said vessel and mounted in the latter, the bottom of the vessel being provided with legs, and the bottom of the receptacle being elevated above the bottom of the vessel, water being introduced in the interspace between the receptacle and vessel, and a lid or cover for the receptacle comprising a water-pan and a porous plate removably attached thereto and having an annular tubular member rising therefrom to serve as a grip and as a means for supplying water to the pan.

698,726. VEHICLE-TIRE. WILLIAM MCANALD, New York, N. Y. Filed Jan. 15, 1901. Renewed Oct. 5, 1901. Serial No. 73,009. (No model.)

Claim.—1. The combination with a wheel-rim having grooves in the sides, of the metallic plates secured to the wheel-rim and having inwardly-projecting ribs or bands adjacent to their inner and outer ends, the wooden tire having grooves in its sides, said grooves being of a width greater than the width of the ribs or bands, the interspace between the rim and tire, and the cavity-bands passing through the plates, and also through the wooden tire, substantially as described.

2. A wheel-tire composed of wood made in sections turned with the end grain and having a central strip or ring also of wood, the grain of which extends in a direction different to the grain of the wooden tire, substantially as shown and described.

3. The combination with a wheel-rim grooved as described, of a wooden tire having a reinforcing central portion and also grooved upon the sides, the metallic plates having inwardly-projecting ribs or bands, the interspace between the wheel-rim and wooden tire, the groove or bands for fastening the plates to the wheel-rim, and the cavity-bands passing through the plates adjacent to their outer ends, the wooden tire being bored out to permit the tire to yield upon the hub, substantially as shown and described.

698,727. ARTIFICIAL BUILDING-STONE. JAMES A. McANALD, Edinboro, Pa. Filed Aug. 22, 1901. Serial No. 71,988. (No model.)

Claim.—1. An artificial building-stone comprising oppositely-

arranged side pieces formed with vertical ways or grooves, and grooves in the walls of the ways, partitions having their ends formed in fit in the ways or grooves and having vertical grooves coincident with them of the walls of the ways in the side pieces, and a binder of cement in the grooves.

2. An artificial building-stone comprising oppositely-disposed side pieces formed with vertical ways or grooves, and grooves in the walls of the ways, and strengthening-ribs on the inner face of the side pieces, partitions having their ends formed to loosely engage in the ways of the side pieces and formed with vertical grooves coincident with the grooves in the walls of said ways, and a cement binder in the registering grooves of the partitions and ways.

698,728. CHASSIS-PRESS. MARSHALL McANALD, Edinboro, Pa., Wm. Filed Dec. 20, 1901. Serial No. 98,907. (No model.)

Claim.—1. In a chassis-press of the type specified, a stationary nut, a screw engaging the nut, a slide in connection with the screw, racks coupled together by the slide, guide-supports for the racks, a follower-block carrier provided with latches engageable with said racks, and means for holding the carrier in adjusted position on disengagement of the latches from the aforementioned racks.

2. In a chassis-press of the type specified, an adjustable head-block, a stationary nut, a screw engaging the nut, a slide in connection with the screw, racks coupled together by the slide, guide-supports for the racks, a follower-block carrier provided with latches engageable with said racks, and means for holding the carrier in adjusted position on disengagement of the latches from the aforementioned racks.

3. In a chassis-press of the type specified, a vertically-adjustable trough, a follower-block carrier, screw-controlled slide-racks, carrier-latches engageable with racks, and means for holding the carrier in adjusted position on disengagement of said latches from the racks.

4. In a chassis-press of the type specified, upper frame-beams, a trough and supporting-standards for the beams and trough, a head-block hasting connected to said beams, a rear bar coupling the aforementioned beams, a bar-engaging screw, a slide in connection with the screw, racks coupled together by the slide, guide-supports for the racks, a follower-block carrier provided with latches engageable with said racks, and means for holding the carrier in adjusted position on disengagement of the latches from the aforementioned racks.

5. In a chassis-press of the type specified, upper frame-beams, standards in connection with the beams, a trough having depending claps for which or the trough itself transverse webs of the standards serve as rests, a head-block hasting connected to said beams, a rear bar coupling the aforementioned beams, a bar-engaging screw, a slide in connection with the screw, racks coupled together by the slide, guide-supports for the racks, a follower-block carrier provided with latches engageable with said racks, and means for holding the carrier in adjusted position on disengagement of the latches from the aforementioned racks.

6. In a chassis-press of the type specified, a stationary nut, a screw engaging the nut, a slide in connection with the screw, racks coupled together by the slide, guide-supports for the racks, a follower-block carrier provided with latches engageable with said racks, means in connection with the carrier, and stops arranged to co-operate with the detents or means

for holding said carrier in adjusted position on disengagement of the latch from the said rack.

698,729. MOTOR-VEHICLE. PATRICK J. McHARR, Keywest, Fla. Filed Sept. 21, 1901. Serial No. 70,000. (No model.)

Claim.—1. In a road-vehicle, the combination with the rear wheel and a platform disposed between the wheels, of rotary suspension means connected to the wheels and resiliently connected to the platform in advance of the axle of the rear wheel.

2. In a road-vehicle, a frame, a platform disposed within the frame, standards on the opposite sides of the platform, shafts journaled in the standards, sprocket-wheels on both ends of the shafts, the rear wheel, sprockets on the rear wheel, chains connecting the sprockets, and means for driving the sprockets.

3. In a road-vehicle, the combination with the rear wheel, and a platform, of sprocket-wheels secured to the rear wheel having standards secured to the platform in advance of the axle of the wheel, resiliently-supported bearing-bones in the said housing, shafts mounted in the bones, sprockets on the outer ends of the shafts, and a chain connecting the sprockets to the sprockets on the rear wheel, whereby the platform is resiliently supported.

4. In a road-vehicle, the combination with the rear wheel and a platform, of sprocket-wheels secured to the rear wheel, resiliently-supported bearings on the platform, shafts in the bearings, sprocket-wheels on the outer ends of the shafts, chains connecting the said sprockets, whereby the platform is resiliently supported, and means to rotate the said shafts and propel the vehicle.

5. In a motor-vehicle, the combination with the rear wheel, of a rectangular vertical frame carried by the wheel, and a resiliently-supported vehicle-body carried by the frame.

6. In a motor-vehicle, the combination with the rear wheel, of a rectangular vertical frame carried by the wheel, a vehicle-body in the frame, suspension-springs between the top of the body and the top of the frame, and cushion-springs under the body and on the lower bar of the frame.

7. In a motor-vehicle, the combination of a vertical rectangular frame having wheel-axles projecting from its side bars, rear wheels mounted thereon, a vehicle-body resiliently supported within and by the frame, sprocket-wheels secured to the rear wheels, a platform resiliently connected to the lower bar of the frame, standards on the platform, resiliently-supported bearing-bones, sprocket-wheels on the outer ends of the shafts, chains connecting the sprocket-wheels and supporting-platform, motor mechanism, and operating means between the motor and the resiliently-mounted shafts to rotate them.

698,780. MOTOR-VEHICLE. JAMES A. McHARR, Keywest, Fla. Filed Mar. 10, 1901. Serial No. 61,101. (No model.)

Claim.—As a new article of manufacture, two long members of flat sheet metal having tapered gripping-points formed integral with the gripping ends of said long members, outwardly-extending segmental extensions formed integral with the long members above the point of pivot, the ends of said extensions being widened to form downwardly-extending legs, the inner edges of which legs are at acute angles to the outer edges of said segmental extensions, and a keeper comprising two flat plates each substantially in the shape of an inverted Y, and said plates having a space between their outer inner surfaces, a handle secured between the upwardly-extending legs of the inverted Y plates, a roller between said plates on each downwardly-extending arm thereof for spacing the same apart, and a pin passing through each of said rollers and plates and having a head formed thereon abutting against the outer faces of each of said downwardly-extending arms for moving said rollers in position, said rollers bearing against the outer edges of each of said segmental extensions throughout every movement thereof and engaging said inner edges of said downwardly-extending legs for limiting the movement of said long members substantially as described.

698,781. NEGATIVE-PLATE HOLDER FOR CAMERAS. EDWARD H. HARRIS, Chicago, Ill. Filed Feb. 2, 1902. Serial No. 88,181. (No model.)

Claim.—1. In a negative-plate holder the combination of a frame, bars arranged to move laterally in the frame, geared racks secured to the ends of the bars, a plurality of gear-wheels pivoted between adjacent racks to engage with the teeth of each rack, and springs attached at one end and respectively to the ends of one of the bars and at the other end to the frame, with the other end of each spring attached to the frame; substantially as described.

2. In a negative-plate holder the combination of a frame, U-shaped bars arranged to move laterally in the frame, geared racks secured to the ends of the bars to move longitudinally in the U-shaped bars, a plurality of gear-wheels

only mounted between adjacent racks to engage with the teeth of each rack and washers rotatably mounted on the pivots of the gear-wheels to maintain the geared racks in place; substantially as described.

3. In a negative-plate holder the combination of a frame, U-shaped bars attached to the inner sides of the frame, cross-bars arranged to move laterally in the frame, geared racks secured to the ends of the cross-bars each geared rack arranged to slide longitudinally in the U-shaped bars, a plurality of gear-wheels pivoted between adjacent racks to engage with the teeth of each rack, washers rotatably mounted on the pivots of the gear-wheels to maintain the geared racks in place, springs attached at one end, respectively, to the ends of one of the bars and an attachment at the other end to the frame, the cross-bars respectively provided with grooves on adjacent sides; substantially as described.

4. In a negative-plate holder the combination of a frame, plate-holding bars arranged to move laterally in the frame, geared racks secured to the ends of the bars and a plurality of gear-wheels pivoted between adjacent racks to engage with the teeth of each rack, each plate-holding bar respectively provided with grooves on the inner side thereof, each groove triangular in cross-section with the front face thereof substantially vertical when the plate-holder is in an upright position; substantially as described.

5. In a negative-plate holder the combination of a frame, plate-holding bars arranged to move laterally in the frame, geared racks secured to the ends of the bars, a plurality of gear-wheels pivoted between adjacent racks to engage with the teeth of each rack, and springs attached at one end respectively to the ends of one of the bars and at the other end to the frame, each plate-holding bar respectively provided with grooves on the inner side thereof, each groove triangular in cross-section with the front face thereof substantially vertical when the plate-holder is in an upright position; substantially as described.

6. In a negative-plate holder the combination of a frame, plate-holding bars arranged to move laterally in the frame, one of each bar provided with steps arranged in pairs at equal distances from the center of the bar, each step respectively provided with grooves on the inner side thereof, each groove triangular in cross-section with the front face thereof substantially vertical when the plate-holder is in an upright position and the other bar provided with a recess on its front face and with a groove on its inner side, each groove corresponding in cross-section with the first-named groove, geared racks secured to the ends of the bars, a plurality of gear-wheels pivoted between adjacent racks to engage with the teeth of each rack, and springs attached at one end respectively to the ends of one of the bars and at the other end to the frame, each plate-holding bar movable in opposite directions; substantially as described.

7. In a negative-plate holder the combination of a frame, plate-holding bars arranged to move laterally in the frame, one of each bar provided with steps arranged in pairs at equal distances from the center of the bar, each step respectively provided with grooves on the inner side thereof, each groove triangular in cross-section with the front face thereof substantially vertical when the plate-holder is in an upright position and the other bar provided with a recess on its front face and with a groove on its inner side, each groove corresponding in cross-section with the first-named groove, geared racks secured to the ends of the bars, a plurality of gear-wheels pivoted between adjacent racks to engage with the teeth of each rack, and springs attached at one end respectively to the ends of one of the bars and at the other end to the frame, a link, a rib in the inner face of the link, each rib provided with holes and a pin removably fitting each hole; substantially as described.

8. In a negative-plate holder the combination of a frame, plate-holding bars arranged to move laterally in the frame, one of each bar provided with steps arranged in pairs at equal distances from the center of the bar, each step respectively provided with grooves on the inner side thereof, each groove triangular in cross-section with the front face thereof substantially vertical when the plate-holder is in an upright position and the other bar provided with a recess on its front face and with a groove on its inner side, each groove corresponding in cross-section with the first-named groove, U-shaped bars attached to the inner face of the sides of the frame, geared racks secured to the ends of the bars to slide longitudinally in the U-shaped bars, a plurality of gear-wheels pivoted between adjacent racks to engage with the teeth of each rack, washers rotatably mounted on the pivots of the gear-wheels to hold the racks in place, and spring attached at one end respectively to the ends of one of the bars and at the other end to the frame; substantially as described.

698,782. SEWING MACHINE. ALBERT A. HARRIS, Boston, Wis. Filed May 23, 1901. Serial No. 61,170. (No model.)

Claim.—A tool of the class described comprising a tubular handle, a reciprocating punch-rod extending through the handle and beyond both ends thereof, a retaining spring seated within the handle and co-

acting with the stem, a punch-needle having a socket member detachably engaging one end of the punch-rod, and a cap detachably fitting one end of the handle over the end of the stem opposite the punch-needle.

698,783. EVAPORATING APPARATUS. GRANT H. WILSON, Mansfield, La. Filed July 13, 1901. Serial No. 60,948. (No model.)

Claim.—1. The combination with a furnace; of a boiler, an inclined bottom therein forming a wall of the combustion-chamber of the furnace, an evaporating-pan, a flue extending therefrom, a flue extending through the boiler and adapted to convey the products of combustion from the furnace to the flue of the pan, tubes connecting the pan with the interior of the boiler, and a valve outlet from the boiler.

2. The combination with a furnace, of a boiler, an inclined bottom therein forming one of the walls of the combustion-chamber of the furnace, an evaporating-pan, a flue thereunder having an outlet, flue extending longitudinally through the boiler and adapted to conduct the products of combustion from the furnace to the flue of the pan, closely arranged cross-strips in the pan, a dam, tubes connecting the pan with the interior of the boiler, whereby juice is permitted to flow into said boiler and surround the flue therein, and a valve outlet from the boiler at the lowest point thereof.

3. The combination with a furnace; of a boiler forming one wall of the combustion-chamber of the furnace, an evaporating-pan, a flue thereunder, means for conducting the products of combustion from the furnace to the flue under the pan, tubes connecting the interior of the boiler with the evaporating-pan whereby juice is permitted to flow into said boiler from the pan, said tubes and boiler being heated by the products of combustion, and an outlet from the boiler.

698,784. FUP-CRACKER. HENRY H. GRAMMERS, Baltimore, Md. Filed Jan. 24, 1902. Serial No. 61,111. (No model.)

Claim.—1. In a nut-cracker, the combination of a pair of handles or levers pivoted to the outer ends thereof, a spring working in cooperation with said handles or levers and serving to normally spread the same apart, and means, carried by the link, for causing the said spring to act equally upon both of said handles or levers.

2. In a nut-cracker, a pair of handles or levers; a link pivoted to

mounted to the outer ends thereof; a spring embracing said link and having its free ends bearing on the handles and normally holding the same apart; and means for causing said spring to act equally upon both of said arms.

3. In a nut-cracker, the combination of a pair of handles or levers, each of said handles having a cross-slot formed therein near its outer end; a link pivotally connected to the outer ends of said handles or levers; a spring having its ends seated in said cross slots or recesses; and means, carried by the link, for causing said spring to act equally upon both of said handles.

4. In a nut-cracker, the combination of a pair of handles or levers, each of said handles having a curved slot or recess F formed upon its inner face near its outer end; a link pivotally connected to the outer ends of said handles; and a spring having its free ends extending into said curved recesses, substantially as and for the purpose described.

5. In a nut-cracker, the combination of a pair of handles or levers; a link pivotally connected to the outer ends thereof, each of said handles being provided with a curved slot or recess extending transversely thereof and in approximate alignment with the inner or lower edge of the link; and a spring for normally holding the levers apart, the free ends of said spring being seated in said curved recesses.

6. In a nut-cracker, the combination of a pair of handles or levers; a link pivotally connected to the outer ends thereof, each of said levers being provided with a curved cross groove or channel F in approximate alignment with the inner or lower edge of the link; and a spring embracing said link and having its free ends seated in the said curved grooves or channels adjacent to the face of the link, substantially as described.

7. In a nut-cracker, the combination of a pair of handles or levers, each provided with a cross groove or channel near its outer end; a link pivotally connected to the outer ends of said handles or levers, said link being formed with a recess or depression in its outer face; and a spring embracing said link and having its free ends seated in the cross grooves or channels in the handles, and likewise having a portion of its body extending through said depression or notch formed in the link, substantially as described.

8. In a nut-cracker, the combination of a pair of handles or levers each provided with a cross groove or channel near its outer end; a link pivotally connected to the outer ends of said handles or levers, said link being provided with a recess G having straight side walls; and a spring comprising a head I, loops K, and loops passing through the notch or recess formed in the link, and diverging arms J, the ends of the arms extending into the cross grooves or channels formed in the handles or levers, substantially as described.

698,785. **SHOCK-COMPRESSOR.** SAMUEL EAST, Fremont township, Madison county, Ohio. Filed Dec. 7, 1901. Serial No. 38,067. (No model.)

Claim.—1. A shock-compressor comprising a frame, two pulleys journaled therein having their active faces turned toward the pulleys, two clamps fabricated therein, combined with a spring connecting the clamps and arranged to draw the active faces of the clamps toward the pulleys, substantially as described.

2. A shock-compressor comprising in combination a frame, two abutments therein over which the ends of a rope are adapted to pass, two clamps independent of said abutments having their active faces turned away from each other and toward said abutments and arranged to clamp the ends of the rope against said abutments, and a spring for yieldingly drawing said clamps toward the abutments to hold the ends of the rope, substantially as described.

698,786. **RAILWAY-VEHICLE FRAME OF THE LIKE.** GEORGE REYNOLDS, Brussels, Belgium, assignor to Societe Anonyme des Wagons Tubulaires, Brussels, Belgium. Filed Dec. 18, 1901. Serial No. 38,571. (No model.)

Claim.—1. In combination with the upper and lower frame members, a support or strut interposed between the same, and clamping said

pieces embracing said frame members, with means for securing said plates together and to said support or strut, substantially as described.

2. In combination, with the upper and lower tubular frame members, an interposed strut or support having ends against which said frame members rest, side clamping-plates embracing said frame members, and bolts passing through said strut and connecting said plates, substantially as described.

698,787. **CONCENTRATOR.** MARK B. ROBINSON, Kingston, Ark. Filed Dec. 27, 1900. Serial No. 41,302. (No model.)

Claim.—1. In a concentrator, the combination of a concentrating-table having along one side a concave trough and superposed water-supply pipe, and having along another portion a line of riffler, extending transversely and tapering in the direction of their length to form central portions of greater thickness than the ends whereby the material at the ends of the riffler is agitated with greater effect than the material at the thickest center, and a deflection-plate extending in line with the trough and below the water-supply pipe, said plate being a series of independent and gradual curves.

2. A concentrator-table having an inclined extension at one end, by which the pulp is fed said extension having a series of deflection said de-

flexion disposed substantially in line with the floor and having one portion fitted to the extension and a second portion made trough-like and capable of spreading the stream over the extension and causing it to carry the lighter portion of material a greater distance along the inclined extension than the heavier portion.

2. The combination with an inclined concentrating-table, of a series of deflection plates at the head end thereof said deflection plates being in line with the floor and having one portion fitted to the table and another portion made trough-like and extending in the direction of the flow of pulp, and means whereby the deflection plates may be adjusted to different angles to suit the character of pulp acted on, and the flow of water.

3. The combination in a concentrator of a concentrating-table A; a series of rows of transversely-placed riffler running from the head of the table to the foot thereof, the said riffler being thick in the center and decreasing in thickness therefrom to the ends thereof; a series of deflection plates rising from the table in gradual curved lines, and extending from the head to the foot of the table; water-supply pipes disposed above said deflection plates and having properly-spaced apertures therein adapted to direct a jet of water on the middle portion of the deflection plates; a concave trough below said pipe and adjacent to the deflection plates to carry off the concentrate.

4. The combination in a concentrator of a concentrating-table A, divided into two parts by the partition-rib D, extending centrally from the head to the foot thereof; a row of transversely-placed riffler on either side of said partition-rib extending from the head to the foot, this at the ends and thick in the middle; deflection plates F extending from the head to the foot, and rising above the table in gradual curved lines; water-supply pipes G, disposed above said deflection plates and having discharge-apertures spaced apart, adapted to direct a jet of water onto the deflection plates, the troughs H below the surface of the table, said troughs adapted to receive and carry off the concentrate; and the inclined portion B at the head of said table and connecting therewith, the said extension being provided with a plurality of deflection plates H, arranged to spread the pulp over the concentrating-table.

5. In a concentrator the combination with a water-supply and a table, of a series of deflection plates along the side of the table and beneath the supply-pipe, and consisting of plates extending above the table and curved in the direction of their length.

698,788. **ELEVATOR.** ALFRED E. BOWEN, Chicago, Ill. Filed Oct. 10, 1901. Serial No. 78,128. (No model.)

Claim.—1. In an elevator, in combination, an electric motor, electric circuit, a brake comprising an electric magnet suspended on one end of a lever pivoted to the car, a stationary structure near-by, a brake-shoe on the other end of said lever, a cam-shoe on the revolving motor parts, and a hand-brake comprising a lever pivoted to the car with hand-brake connections within the drum, substantially as described.

2. In an elevator, in combination, an electric motor, electric circuit, a brake comprising a broken electric circuit, with three or more separated contact-strips interposed in the broken circuit, an angular block pivoted to the car with contact-strips in pairs projecting from its angle sides, a brake comprising an electric magnet suspended on one end of a lever pivoted to the car, a stationary structure near-by, a brake-shoe on the other end of said lever, a cam-shoe on the revolving motor parts, substantially as described.

3. In an elevator, in combination, vertical guides, screw-rolls, a drum-arrange mounted in the shaft, a rope of anti-friction-balls bearing on the drum, the car between the guides and bearing on the balls, an electric motor with the car, electric circuit, a brake comprising an electric magnet suspended on one end of a lever pivoted to the car, a stationary structure near-by, a brake-shoe on the other end of said lever, a cam-shoe on the revolving motor parts for the purpose set forth.

4. In an elevator, in combination vertical guides, screw-rolls, a drum-arrange mounted in the shaft, a rope of anti-friction-balls bearing on the drum, the car between the guides and bearing on the balls, an electric motor with the car, electric circuit, a controller comprising a broken line-circuit, three or more contact-strips interposed in the broken circuit, an angular block pivoted to the car with contact-strips in pairs projecting from its angle sides for closing the motor, substantially as described.

5. In an elevator, in combination, vertical guides, screw-rolls, a drum-arrange mounted in the shaft, a rope of anti-friction-balls bearing on the drum, the car between the guides and bearing on the balls, the counter-weighted car having ball-bearing connections with the drum, an electric motor with the car, electric circuit, a brake comprising an electric magnet suspended on one end of a lever pivoted to the car, a stationary structure near-by, a brake-shoe on the other end of said lever, a cam-shoe on the revolving motor parts, for the purpose set forth.

6. In an elevator, in combination, vertical guides, screw-rolls comprising a series of studs with anti-friction-rollers thereon, a drum-arrange mounted in the shaft, a rope of anti-friction-balls bearing on the drum, the car between the guides and bearing on the balls, an electric motor with the car, electric circuit, a controller comprising a broken line-circuit, with three or more separated contact-strips interposed in the broken circuit and an angular block pivoted to the car with contact-strips in pairs projecting from its angle sides, a brake comprising an electric magnet suspended on one end of a lever pivoted to the car, a stationary structure near-by, a brake-shoe on the other end of said lever, a cam-shoe on the revolving motor parts, substantially as described.

7. In an elevator, in combination, vertical guides, screw-rolls comprising a series of studs with anti-friction-rollers thereon, a drum-arrange mounted in the shaft, a rope of anti-friction-balls bearing on the drum, the car between the guides and bearing on the balls, an electric motor with the car, electric circuit, a controller comprising a broken line-circuit, with three or more separated contact-strips interposed in the broken circuit and an angular block pivoted to the car with contact-strips in pairs projecting from its angle sides, a brake comprising an electric magnet suspended on one end of a lever pivoted to the car, a stationary structure near-by, a brake-shoe on the other end of said lever, a cam-shoe on the revolving motor parts, and a hand-brake comprising a lever pivoted to the car with hand-brake connections within the drum, substantially as described.

8. In an elevator, in combination, vertical guides, screw-rolls comprising a series of studs with anti-friction-rollers thereon, a drum-arrange mounted in the shaft, a rope of anti-friction-balls bearing on the drum, the car between the guides and bearing on the balls, an electric motor with the car, electric circuit, a controller comprising a broken line-circuit, with three or more separated contact-strips interposed in the broken circuit and an angular block pivoted to the car with contact-strips in pairs projecting from its angle sides, a brake comprising an electric magnet suspended on one end of a lever pivoted to the car, a stationary structure near-by, a brake-shoe on the other end of said lever, a cam-shoe on the revolving motor parts, and a hand-brake comprising a lever pivoted to the car with hand-brake connections within the drum, substantially as described.

698,789. **METHOD OF EXTRACTING METALS FROM THEIR OXIDE STATE.** JOHN BERNARD and JOHN LAMAR, Stockholm, Sweden, assignors to Albin Janki, Stockholm, Sweden. Filed Dec. 11, 1901. Serial No. 68,944. (Specimen.)

Claim.—A process for producing isotropic or other bodies which are hard, do not fall into pieces at a high temperature and are suitable for reduction, consisting in mixing pulverized acid ores, carbon, hydrocarbon and an organic nitrogen compound or compounds, pressing the mixture to bodies of suitable shape and finally heating said bodies to 900° to 1000° centigrade.

698,790. **CAR-COUPLING.** ROBERT H. ROBINSON, Marion, Oreg. Filed Feb. 7, 1901. Serial No. 45,398. (No model.)

Claim.—1. In a car-coupler, the combination with a draw-bar comprising a plurality of draft-ends, each of said ends consisting of joined sections, one section of each end being elastically and yieldingly connected to the car, of a coupling-head secured to the other section, a rock-shaft mounted upon the car and provided with a plurality of offsetting arms, and sliding connections between the arms and the outer sections of the draw-bar.

2. In a car-coupler, the combination with longitudinally-disposed spaced guide-bearings rigidly secured to the under side of the car, of a stationary transverse supporting-beam located between the guide-bearings, a plurality of draft-ends passing through said transverse beams, said ends

Claim.—1. In a bridge, the combination with a crown-strap and chest-strap, of a brow-band formed with a central loop, a cross-brace having a central loop, and a crown-billet depending from the center of the crown-strap and passed through the loops in the brow-band and cross-brace-strap, said billet being provided with shoulders against which the looped portion of the cross-strap contacts, and fastening means passed through the loop of the brow-band and the billet.

2. In a bridge, the combination with a crown-strap, and chest-strap having washers attached thereto, of a brow-band formed with a central loop, a cross-brace-strap terminally secured to the upper portion of the washers and also having a central loop, and a crown-billet depending from the center of the crown-strap and passed through the loops in the brow-band and cross-brace-strap, the said billet immediately below the cross-brace-strap being broadened to provide opposite shoulders against which the lower edge of the looped portion of cross-strap contacts and is thereby drawn close against the lower edge of the brow-band, and fastening means passed through the loop of the brow-band and the portion of the billet engaged thereby.

698,748. SULFUR CANDLE. CHARLES H. SHAW, Brooklyn, N. Y., assignor to Robert H. Thompson, New York, N. Y. Filed May 10, 1901. Serial No. 98,612. (No model.)

Claim.—1. A sulfur candle having in its upper surface a cavity and a wick arranged with one side surrounded by the solid mass of sulfur, but the other side open to or only slightly separated from said cavity.

2. A sulfur candle having in its upper surface a central cavity, and a wick arranged with its outer side surrounded by the solid mass of sulfur but the inner side open to or only slightly separated from said cavity.

3. The combination of a container having circumferential grooves and a sulfur candle having horizontally-extended surfaces which fit in said grooves.

4. The combination of a container, a sulfur candle therein, and means provided in a wall of the container which engage with the candle for holding the candle in the container.

5. The combination of a container serving as a mold, sulfur cast in said container to form a candle, and means provided in the container which is engaged by the sulfur of the candle to prevent the sulfur from leaving the container after the sulfur has set.

698,749. TYPE-WRITING MACHINE. LOUIS BRULIN, Milwaukee, Wis., assignor to C. Latham Stokes Typewriter Manufacturing Company, Milwaukee, Wis., a Corporation of Wisconsin. Filed May 10, 1901. Serial No. 98,577. (No model.)

Claim.—1. In a type-writing machine the combination of a series of angular type-bars having pivot-arms which are capable of turning and moving endwise, each of said arms being provided on opposite sides with fingers, a fixed guide-plate having a series of angular slots with which the fingers on one side of said arms engage, and slides having oblique

slots engaging the fingers on the opposite side of said arms, substantially as described.

2. In a type-writing machine the combination of a series of angular type-bars having pivot-arms capable of turning and moving endwise and provided with fingers, a guide-plate having a series of angular slots engaging fingers on said arms, and a series of slides arranged in planes at different distances from said arms and provided with oblique slots engaging fingers on said arms, substantially as described.

3. In a type-writing machine the combination of a series of angular type-bars having pivot-arms capable of turning and moving endwise and provided with fingers, a fixed plate or frame parallel with said pivot-arms, and overlapping slides detachably connected with said plate in different planes and provided with cam-slots engaging said fingers, substantially as described.

4. In a type-writing machine the combination of angular type-bars having pivot-arms capable of turning and moving endwise and provided with fingers, a fixed plate or frame parallel with said arms and having openings through which said fingers project, and slides having oblique slots which engage said fingers and detachably connected with said plate and guided by turn-bushes which engage longitudinal slots in said slides, substantially as described.

5. In a type-writing machine the combination of angular type-bars having pivot-arms capable of turning and moving endwise and provided on opposite sides with fingers, a front plate having angular slots engaging the fingers on one side of said arms, a back plate having openings through which the fingers on the opposite side of said arms project, and slides arranged in different planes on the rear side of said back plate and having oblique slots engaging with the rearwardly-projecting fingers of said arms, substantially as described.

6. In a type-writing machine the combination of a series of angular type-bars having type-arms of different lengths and pivot-arms capable of turning and moving endwise and provided on opposite sides with fingers, a guide-plate arranged in front of and parallel with said arms and having angular slots engaging with the forwardly-projecting fingers, a back plate arranged behind and parallel with said arms and having openings through which the rearwardly-projecting fingers thereof project, and slides detachably connected with said back plate and held and guided in different parallel planes by shouldered turn-bushes pivoted in said back plate and engaging longitudinal slots in said slides, which are also provided with oblique slots engaging the rearwardly-projecting fingers of said pivot-arms, substantially as described.

7. In a type-writing machine the combination of angular type-bars having type-arms of different lengths and pivot-arms capable of turning and moving endwise and provided with forwardly-projecting fingers, a guide-plate having angular slots, the horizontal portions of which are directly opposite said pivot-arms, whose fingers engage therewith, and means for turning each pivot-arm and moving it endwise to produce an

impression on the plates of the character with which the corresponding type-arm is provided, substantially as described.

8. In a type-writing machine the combination of angular type-bars having type-arms of different lengths and pivot-arms capable of turning and moving endwise and provided with fingers, slides arranged at different distances from said pivot-arms and having oblique slots engaging with said fingers, key-levers and auxiliary levers connected with said slides and at different distances from their fulcrums with said key-levers, substantially as described.

698,750. LOG-TURNING. JOHN J. SCHUMER, Palo Alto, Cal., assignor of one-half to J. H. Henry, San Jose, Cal. Filed Dec. 12, 1901. Serial No. 98,695. (No model.)

Claim.—1. A log-turning apparatus comprising a tilting frame, carrying a toothed chain, a constantly-rotating gear-pulley, a pair of pulleys in proximity thereto, connections from one of said pulleys to the tilting frame, connections from the other pulley to the toothed chain, a single operating-lever, and independent connections from said lever for causing said pulleys to engage with said gear-pulley.

2. A log-turning apparatus comprising a tilting frame, carrying a toothed chain, a constantly-rotating pulley, a pair of pulleys in proximity thereto, connections from one of said pulleys to the tilting frame, connections from the other pulley to the toothed chain, a single operating-lever, a rock-shaft, to which said lever is pivoted, connected to one of said pair of pulleys, a rod, to which said lever is pivoted, connected to the other of said pulleys, said lever acting as a crank to turn the rock-shaft, and as a lever fulcrumed to the rock-shaft for operating the said rod.

698,751. BRACK-BLANK AND CHAFF-IRON HOLDER. ALMA P. SMITH, JR., Brooklyn, Mass., assignor to Boston Roller Chaff Iron Company, Boston, Mass., a Corporation of West Virginia. Filed Nov. 14, 1901. Serial No. 98,216. (No model.)

Claim.—An article of manufacture, a carriage part having a conical central portion comprising a lower-body and roller-supporting arm projecting laterally therefrom, and two transverse members and portions projecting in opposite directions from said conical central portion, substantially as described and for the purposes specified.

698,752. MACHINE FOR TURNING GASTER-WHEELS. ARTHUR SMITH, Chicago, Ill. Filed Dec. 2, 1901. Serial No. 98,696. (No model.)

Claim.—1. In a machine of the kind specified, the combination with the frame, right bearing-plates carried thereby, and spindles carrying outer-hubs journaled in said bearing-plates, of clamping-plates movably mounted on said frame and movable toward and away from said bearing-plates, openings in said clamping-plates through which said outer-hubs pass to act on a block carried between said clamping-plates, and devices for engaging said block through said openings in one of said clamping-plates to receive and hold the pieces cut out of said block by said outer-hubs.

2. In a machine of the kind specified, the combination with two sets of bearing-plates, each having a plurality of spindles journaled therein, and outer-hubs on said spindles adapted to cut on opposite sides of a block of wood or other material, of clamping-plates between said bearing-plates adapted to carry said block, openings in said plates through which said outer-hubs pass, devices engaging said block through said openings to receive and hold the pieces cut out of said block, and means for imparting relative motion to said clamping-plates and said bearing-plates toward and away from each other.

3. In a machine of the kind specified, the combination with two sets of bearing-plates, a plurality of spindles journaled therein, and outer-hubs on said spindles adapted to operate on opposite sides of a block of wood or other material to be cut, of clamping-plates between which the block is adapted to be held, openings in said plates through which said outer-hubs pass, a plate carrying pins adapted to pass through said openings in one of said plates to engage the partially-cut pieces, means for holding said plate in place, and means for moving said clamping-plate toward and away from said bearing-plates.

4. In a machine of the kind specified, the combination with two sets of bearing-plates, spindles journaled therein, and outer-hubs on said spindles, of clamping-plates between which the block to be cut is clamped, openings in said plates for the passage of said outer-hubs, and spring-actuated pins mounted in one of said clamping-plates between the openings therein, adapted to bear upon the block with a yielding pressure, whereby irregularities in the surface of the block are prevented from decreasing the clamping action of said plates, substantially as described.

5. In a machine of the kind specified, the combination with two bearing-plates and a series of spindles journaled therein, of a pulley on each of said spindles between said plates, each of said pulleys being provided with circumferential flanges between its ends dividing the face of same into three parts, of three belts trained over each of said pulleys, two of said belts engaging the end portions of the face of each of said pulleys on one side, and the other of said belts engaging the middle portion of said pulley on the opposite side, whereby said pulleys are turned by said belts on the bearings of said spindles will be contained.

698,753. MOTOR-VEHICLE. GEORGE W. SMITH, Martins, Mo.
Filed Aug. 24, 1901. Serial No. 73,463. (No model.)

Claim.—1. In a motor-vehicle, the combination with a stationary axle-frame, of a rear axle secured thereto, a movable axle-frame having a pivotal connection with the rear axle, a rotational axle-shaft mounted on each frame, said axles being connected by compensating gearing, and a driving-shaft mounted longitudinally of the rear axle and geared at its opposite ends to the axle-shafts.

2. In a motor-vehicle, the combination with a stationary axle-frame, of a rear axle secured thereto, a movable axle-frame having a pivotal connection with the rear axle, a rotational axle-shaft mounted on each frame, said axles being connected by compensating gearing, and a rotational driving-shaft mounted longitudinally of the rear axle and geared at its opposite ends to the axle-shafts, the axles of said driving-shaft being connected by compensating gearing.

3. In a motor-vehicle, the combination with a stationary axle-frame, of a rear axle secured thereto, a bracket fastened to the free end of the rear axle, a movable axle-frame having a pivotal connection with the bracket, an axle-shaft mounted on each frame, and a driving-shaft mounted longitudinally of the rear axle and having gear connections with the axle-shafts.

4. In a motor-vehicle, the combination with a stationary axle-frame, of a rear axle secured thereto, a bracket fastened to the free end of the rear axle and depending below the same, a movable axle-frame having a pivotal connection with the bracket, an axle-shaft mounted on each frame, and a driving-shaft mounted longitudinally of the rear axle and having a gear connection with the axle-shafts.

5. In a motor-vehicle, the combination with a stationary axle-frame, of a rear axle secured thereto, a bracket fastened to the free end of the rear axle and having projecting arms, an axle-frame pivoted to the arms, an axle-shaft journaled upon the pivoted frame and comprising sections connected by compensating gearing, an axle-shaft journaled upon the arms of the bracket and carrying a gear-wheel that meshes with the compensating gearing, and a driving-shaft having a gear connection with the axle-shafts.

6. In a motor-vehicle, the combination with an axle-frame, of a rear axle comprising bars secured to the frame, said bars being arranged in convergent relation toward their free ends, a journal-box connecting the convergent ends of the bars, a driving-shaft journaled in said box, an axle-frame pivoted to the free end of the rear axle, an axle journaled in the frame, and gear connections between the driving-shaft and the axle.

7. In a motor-vehicle, the combination with an axle-frame, of an axle-shaft journaled on the frame, a rear axle comprising bars secured to the frame and arranged in convergent relation toward their free ends, a journal-box connecting the convergent ends of the bars, a driving-shaft journaled in said box and geared to the axle-shaft, an axle-frame pivoted to the free end of the rear axle, an axle journaled in the frame, and gear connections between the driving-shaft and the axle, said connections being concentric with the pivot-axis of the frame.

8. In a motor-vehicle, the combination with an axle-frame, of an axle-shaft journaled on the frame, a rear axle comprising spaced bars secured to the frame, a journal-box connecting the free ends of the bars, a bracket secured to the axle-box, an axle-frame pivoted to the bracket, an axle-shaft journaled on the pivoted frame, a driving-shaft mounted in the journal-box of the rear axle, and gear connections between the driving-shaft and the axle-shafts of both frames.

9. In a motor-vehicle, the combination with a pair of axle-frames, of a rear axle connecting the frames, axles journaled upon the frames, a driving-shaft journaled upon the rear axle, compensating gearing located upon the driving-shaft, one of the gears thereof being secured to the shaft, the other being loosely mounted on said shaft, a master-wheel also loosely mounted to the driving-shaft and carrying pinions meshing with the gears and loose wheels, said master-wheel having teeth on its periphery, and a gear-wheel fastened to the loosely-mounted gear and having an operative connection with one of the axles.

10. In a motor-vehicle, the combination with an axle-frame comprising aligned casing-sections, of an axle-shaft journaled in the aligned casing-sections, a sleeve rotatably mounted on the axle-shaft and located in one of the casing-sections, wheels secured to the sleeve and shaft, and compensating gearing connecting the sleeve and shaft.

11. In a motor-vehicle, the combination with an axle-frame comprising aligned sections, spaced apart and connected by a transverse, of an axle-shaft rotatably mounted in the aligned casing-sections, a sleeve journaled upon the axle-shaft, said sleeve being located in one of the casing-sections and projecting beyond both ends thereof, a wheel secured to the outer projecting end of the sleeve, compensating gearing connecting the inner projecting end of the sleeve and the shaft, and a wheel secured to the outer end of said shaft.

12. In a vehicle, a front axle-frame, a rear axle-frame, a rear axle rigidly secured to the rear axle-frame, a bracket swivelled upon the rear axle, the front axle being pivoted to the bracket.

13. In a vehicle, a front and rear axle, a rear axle secured to one axle-frame and a bracket having journals located in angular relation, one of said journals being swivelled upon the rear axle, the other axle-frame being pivoted in the other journal.

14. In a motor-vehicle, the combination with a rear axle, of a driving-shaft journaled longitudinally thereon, an axle-frame having a swivelled connection with the rear axle to permit of its upright swinging movement, an axle journaled upon the frame, and connections between the axle and the driving-shaft.

15. In a motor-vehicle, the combination with a rear axle, of a driving-shaft journaled longitudinally thereon, a bracket swivelled upon the rear axle, an axle-frame pivoted to the bracket, an axle journaled upon the frame, and a stub-shaft mounted on the bracket and connecting the axle and driving-shaft.

16. In a motor-vehicle, the combination with a rear axle having spaced journal-boxes, of a bracket having journals swivelled in the boxes, a driving-shaft passing through the journals of the bracket, an axle-frame pivoted upon the bracket, an axle journaled on the frame, and a stub-shaft rotatably mounted on the bracket and connecting the axle and driving-shaft.

698,754. STATION-INDICATOR. WILLIAM SMITH, Ruston, La., assignor of one-half to Peyton Opel Robinson, Ruston, La. Filed Dec. 18, 1901. Serial No. 68,788. (No model.)

Claim.—1. In a station-indicator, a roller, a ratchet fast on the shaft thereof, a sprocket-wheel having a flange, a casing on said flange, and a spring-actuated pawl in said casing having beveled side and an operating-lever and pointer, as set forth.

2. In a station-indicator, a roller, a ratchet fast thereon, a sprocket loose on said shaft, a drum fast with the sprocket, a pawl-casing, a spring-actuated pawl carried by the sprocket and engaging the ratchet, said pawl being reversibly mounted in its casing, and an operating-lever reversibly connected with said drum, as and for the purpose specified.

3. The combination with the roller and its shaft and a ratchet fast on said shaft, of a sprocket and drum loose on the said shaft, a reversible pawl carried by the sprocket to engage the ratchet, a pointer carried by the pawl and a casing for the pawl having a projecting flange provided with notches, as and for the purpose specified.

4. In a station-indicator, a casing having a chamber at its upper end, a curved operating means embodying a sprocket-wheel, a ratchet and a pawl carried by the sprocket and engaging the ratchet and a gear and its actuating device, a cord connecting the same with the curved operating mechanism, and passed through said chamber and a spring within said chamber connected with the said cord to return the parts to their normal position, a pointer carried by said pawl, and a casing for the pawl having a notched flange, as set forth.

and position, a pointer carried by said pawl, and a casing for the pawl having a notched flange, as set forth.

5. The combination with the curved operating mechanism, of a cord connected therewith, a bell-crank lever connected with said cord, a bell, a hammer-arm and an arm pivotedly connected therewith having an outwardly-projecting spring and an inclined outer face to be engaged by the bell-crank lever, as set forth.

6. The combination with a bell, a hammer-arm, an arm pivoted thereto, and a spring acting upon said arm, of a bell-crank lever having one end to engage said arm near the pivotal connection of the two, curved operating mechanism, and a connection between the same and the bell-crank lever, as and for the purpose specified.

698,755. VEHICLE OR POT FOR GATHERING FISHES FROM THROWN OFF SWIMMING-MACHINES. GEORGE BRUNDA, Baltimore, Germany. Filed Sept. 2, 1902. Serial No. 20,304. (No model.)

Claim.—1. In combination, the rim having an upwardly-struck bottom forming a double angular edge, a reinforcing-band in said edge, a plurality of elastic pieces having their upper edges resting against the upwardly-struck bottom and their lower edges projecting below the edge of the rim, clamping-pieces clamping against the inner faces of the elastic pieces and being for clamping the same to the rim, substantially as described.

2. A spinning-pot or the like having an upwardly-struck bottom with an open center, a downwardly-struck flange at the edge of said open center and a closing-disk having an inwardly and downwardly bent flange designed to abut against the inclined flange surrounding the open center, substantially as described.

3. A spinning-pot or the like having an upwardly-struck bottom with an open center, a downwardly-struck flange at the edge of said open center, a closing-disk having a correspondingly-struck flange resting upon the first-mentioned inclined flange, said closing-disk being removable, substantially as described.

698,756. FLY-SCREEN. ARTHUR L. GOSCHENSKY, South Springs, Ind. Ter. Filed Nov. 22, 1901. Serial No. 24,321. (No model.)

Claim.—1. In a screen, the combination with a screen-frame, and a sheet of screen material, of triangular blocks interposed between the frame and the screen material, and a horizontal bar arranged above the blocks and provided along its front face with transverse recesses forming fly-catches, the front of said recesses being covered with screen material, substantially as described.

2. In a screen, the combination with a screen-frame, and a sheet of screen material, of triangular blocks interposed between the screen material and the frame, a horizontal bar arranged above the blocks and provided along its front face with transverse recesses forming fly-catches and covered at the front with the wire-gauze, and the flanges arranged at the upper ends of the recesses and adapted to prevent the return of flies, substantially as described.

3. In a screen, the combination with a screen-frame, and a sheet of screen material, of blocks interposed between the screen material and the frame, a horizontal bar arranged above the blocks and provided along its front face with transverse recesses forming fly-catches, said recesses being covered at the front by screen material, and the latter being extended above the transverse bar to form a flange, and a strip of screen material extending upward from the bar at the inner sides of the recesses, substantially as described.

4. In a device of the class described, a horizontal bar designed to be applied to an ordinary window-screen and provided at its front face with transverse tapering recesses forming fly-catches, said recesses being covered at the front by the screen material when the bar is in position, and an inner strip secured to the outer edge of the horizontal bar and having a projecting flange to cooperate with the screen material of a screen, substantially as described.

698,757. SELF-HEATING GAS-BURNER. BRIAN S. SWANER, Worcester, Ohio. Filed Apr. 20, 1901. Serial No. 54,671. (No model.)

Claim.—1. In a hollow end-iron, having a burner-tube longitudinally within it, opening outwardly, the independently-removable gas-conducting apparatus comprising a fluid-conductor, and a valve-regulated gas-conducting pipe leading therefrom to the open end of said burner-tube, and means for adjustably and removably securing said apparatus in position independently of said burner-tube and connection, substantially as set forth and for the purpose specified.

2. The combination with a hollow end-iron, having a burner-tube extending longitudinally therein, opening outwardly through, and rigidly connected with the rear wall of said end-iron; of a capenable gas-conducting apparatus adjustably therein, having a gas-conducting pipe adapted

by bands therein, to hang removably suspended in case thereof, upon and over the opposite ends of said iron-body; and a removable cover, fitted to inclose said body, and rest upon, and removably fasten said pipe therein by bearings on said cover, substantially as shown and described and for the purpose specified.

3. In a hollow end-iron, having a burner-tube lengthwise within it, opening rearwardly, the independently-removable gas-generating apparatus comprising a fluid-reservoir and a valve-regulated gas-pipe leading therefrom to the mouth of said burner-tube—said pipe bent and shaped to hang upon and over, and extending beyond the opposite ends of said end-iron respectively, said ends provided with seats as a saddle to receive the downwardly-bent portions of said pipe fitted thereto, and removably held said apparatus in position to convey gas through and from said pipe directly into said burner-tube, substantially as shown and described and for the purpose specified.

4. The combination with a hollow end-iron, having a burner-tube extending lengthwise therein, opening outwardly; of the independently-removable gas-generating apparatus—comprising a fluid-reservoir and a valve-regulated gas-conducting pipe leading therefrom to the open end of said burner-tube—said pipe bent and shaped to hang upon and over, and extending beyond the opposite ends of said end-iron respectively, said ends provided with seats as a saddle, to receive the downwardly-bent portions of said pipe fitted thereto; and a projecting catch or brace at the rear end of said iron, adapted to engage the lower end of said apparatus, to adjustably and removably hold the same in position to convey gas from said pipe directly into the open end of said burner-tube, substantially as set forth, and for the purpose specified.

5. The combination with a hollow end-iron, having a burner-tube extending lengthwise therein, opening outwardly; of the independently-removable gas-generating apparatus comprising a fluid-reservoir and a valve-regulated gas-conducting pipe leading therefrom to the mouth of said burner-tube—said pipe having bands adapted to hang upon and over the opposite ends of said iron-body, said ends provided with seats as a saddle, to receive the downwardly-bent portions of said pipe fitted thereto; and a projecting catch or brace, to adjustably engage the lower end of said apparatus; and a removable cover detachably secured upon the body of said end-iron, having a bearing at each end adapted to rest upon and removably fasten said apparatus for operation, substantially as set forth, and for the purpose specified.

6. The combination with a hollow end-iron having a burner-tube extending lengthwise therein, and a gas-generating apparatus connected therewith; of means for ventilation and combustion comprising ingross air-vents along, at or near the upper part of the respective sides of said end-iron body, and egress-vents for the gases of combustion through, and along, at or near the longitudinal center of the cover of said end-iron, a shield B, attached, with intervening open space, above said cover; and a handle, H, above said shield, substantially as set forth, and for the purpose specified.

7. The combination with a hollow end-iron, having a burner-tube extending lengthwise therein, and ingross air-vents along, at or near the upper part of the sides thereof; of the separable gas-generating apparatus comprising a fluid-reservoir and a valve-regulated gas-conducting pipe leading therefrom to the mouth of said burner-tube by suitable bands in said pipe, and by said bands removably secured in position separate and separable from said burner-tube and connections; and a removable cover for said iron-body, provided with egress-vents therein for the escape of the gases of combustion, along at or near the longitudinal center of said cover; a shield above said cover adapted in form therewith a flue for draft outwardly from said egress-vents, and a handle above said shield, substantially as set forth, and for the purpose specified.

8. The combination with a hollow end-iron, having a burner-tube extending lengthwise therein, opening through, and suitably connected with the rear end of said iron-body, and separate from the gas-generating pipe and connections—said body having air-vents at each side thereof at or near the top, and provided with runs slanting downwardly toward each other at each end, as a saddle; of the independently-removable gas-generating apparatus—comprising a fluid-reservoir and gas-conducting pipe with valve, leading therefrom in bands adapted to fit and hang in said saddle, and terminating with a small orifice; an external brace or support for said pipe at the rear end of said body; and a removable cover with handle thereon, fitted to rest upon and removably fasten down said gas-conducting pipe, and having air-vents therein, substantially as shown and described, and for the purpose specified.

698,758. CORE-MAKING MACHINE. RALPH E. THOMAS and FRED CLARK, Alhambra, Pa. Filed Aug. 14, 1900. Serial No. 94,944. (No model.)

Claim.—1. In a core-making machine, a core-box open at top to receive

molten sand and discharge cores, in combination with a cover adjustable over the top of the core-box, one or more plungers working through the bottom of the core-box and of length sufficient to reach the top thereof, a stop regulating the lowermost position of the plunger or plungers in the core-box, a stop for limiting the upward movement of the plunger or plungers in pressing the cores said stop being removable when the cores are complete, and means for moving the plunger or plungers upward in the core-box to press the sand into cores and, after the removal of the sand and removable stop, to expel said cores.

2. In a core-making machine, a core-box open at top to receive sand and discharge cores, in combination with a cover adjustable over the top of the core-box, one or more plungers working through the bottom of the core-box and of length sufficient to reach the top thereof, an adjustable stop regulating the lowermost position of the plunger or plungers in the core-box, a stop for limiting the upward movement of the plunger or plungers in pressing the cores said stop being removable when the cores are complete, and means for moving the plunger or plungers upward in the core-box to press the sand into cores and, after the removal of the cover and removable stop, to expel said cores.

3. In a core-making machine, a table, as A, for holding loose sand having an opening, as A', in combination with a core-box receiving banking B secured to the table and adapted to support a core-box with its top edge flush with the table, a core-box, as C, open at top to receive sand and discharge cores, one or more plungers working through the bottom of the core-box and of length sufficient to reach the top edge thereof, a stop regulating the lowermost position of the plungers in the core-box, means for moving the plungers in the core-box, a removable top for limiting the upward movement of the plungers when compressing the sand, a sliding cover for the core-box and means for covering it on top of the same during compression.

698,759. FENCE-POST. LOUIS A. THOMSON and ADA L. DANIEL, Oak City, Ind. Filed June 14, 1901. Serial No. 64,555. (No model.)

Claim.—1. A fence-post comprising main upright having a base, a second upright pivotally connected to the first upright for movement in the same plane therewith and out of contact with the first upright, said second upright having patches therein to receive fence-wires and being slidably connected with the first upright to permit of adjustment thereof vertically to hold the fence-wires at different elevations, means for holding the second upright at different points of traveling movement, and means for holding the uprights in mutual contact.

2. A fence-post comprising a main upright having a base, a second

upright movably connected with the first upright to permit of engagement of fence-wires between the uprights, and U-shaped clamps engaged in pairs around both members, said clamps having each terminal clamping-jaws for clamping stay-wires of the fence against the cooperating clamp, and retaining-bolts engaged through each pair of clamps between the terminal jaws and the uprights.

3. A fence-post comprising a fixed upright having a block slidably mounted thereon and having means for holding it against sliding movement, said block having also spaced perforated ears, a second upright pivoted at its lower end between the ears for movement in the same plane with the first upright, and means for holding the uprights in mutual contact.

698,760. WINDOW-OPENER. JAMES H. TAYLOR, Alhambra, Cal. Filed Sept. 12, 1900. Serial No. 20,990. (No model.)

Claim.—In a window-opener a brace made with a fork at one end to receive a window-cord and an eye at the other to receive a pin or screw, said eye loosely counterbored and pivoted in a window-jamb immediately behind the window-head, a pocket formed in said jamb to receive said brace, substantially as shown and described and for the purpose set forth.

698,761. PROCESS OF PRODUCING CAMPHOR. EATHELMER TAYLOR, Newark, N. J., assignor, by mesne assignments, to the Portcharter Chemical Company, a Corporation of New York. Filed Aug. 6, 1901. Serial No. 34,696. (Specimens.)

Claim.—1. The process of producing campher, which consists in acting on turpentine with oxalic acid at a suitable temperature.

2. The process of producing campher, which consists in heating anhydrous turpentine with anhydrous oxalic acid.

3. The process of producing campher, which consists in acting on turpentine with oxalic acid, producing bursol and campher, and then oxidizing the bursol to convert it into campher.

4. The process of producing campher, which consists in acting on turpentine with oxalic acid, acting on the resulting mixture with lime, and distilling to separate the bursol and campher, and oxidizing the bursol to convert it into campher.

5. The compound, playl formula, resulting from the action of oxalic acid on turpentine, and having the following structural formula:

said compound having a boiling-point at six hundred and eighty millimeters vacuum, of 100° to 105° centigrade, solidifying below—17° centigrade—decomposed on heating into bursol and carbon monoxide, and decomposed on heating with caustic alkali solution into hydrocarbons and a ferrous.

698,762. WINDOW BRACKET OR STOP. IRVING TOW, South Norwalk, Conn. Filed Oct. 4, 1901. Serial No. 77,693. (No model.)

Claim.—1. In a window stop or bracket, the combination with a window, of means for engaging a window-frame and the lower rail of a

cash, and effective to support the lower ends of said stanchions; means for engaging the upper rail of the cash and effective to support the upper ends of the stanchions; and a stop carried by said stanchions.

2. In a window stop or bracket, the combination with stanchions of means for engaging a window-frame and the lower rail of a cash, and effective to support the lower ends of said stanchions; of means for engaging the upper rail of the cash and effective to support the upper ends of the stanchions; and a stop adjustable on said stanchions.

3. In a window stop or bracket, the combination with stanchions adapted to be supported by a cash; of a stop carried by said stanchions on each side of said cash.

4. In a window stop or bracket, the combination with a stanchion adapted to be automatically clamped upon and supported by a cash; of a stop carried by the stanchion.

5. In a window stop or bracket, the combination with upright stanchions supporting a stop, of a bracket carried by the lower portions thereof and provided with a stop-face to bear against the under side of a cash-rail; another bracket carried near the upper end of said stanchion and provided with a clamp embodying a dog pivoted to swing toward the stanchion and bear against one side of a rail the stop-face to bear against the other side of said rail, a weighted arm projecting from the dog for normally and automatically swinging the dog away from said stanchion, said dog normally clamping against the rail when the latter raises the weighted arm.

6. In a window stop or bracket, the combination of stanchions, means for supporting said stanchions upon a window-cash; of a stop carried by said stanchions on the side of said cash opposite to that on which the stanchions are supported.

7. In a window-bracket, the combination of stanchions; a frame secured thereto; a stop-face carried by the frame, and adapted to bear against one side of a cash-rail; a dog pivoted to swing toward and from said stop-face, and to bear against the other side of said rail; and means effective to automatically swing said dog.

8. In a window-bracket, the combination of stanchions; a frame secured thereto; a stop-face carried by the frame, and adapted to bear against one side of a cash-rail; a dog pivoted to swing toward and from said stop-face, and to bear against the other side of said rail; and means effective to normally and automatically swing said dog away from said stop-face and upon the entry of the cash-rail between said dog and stop-face to swing said dog toward said rail.

9. In a window-bracket, the combination of stanchions; a frame adjustably secured thereto; an adjustable stop-face carried by the frame, and adapted to bear against one side of a cash-rail; a dog pivoted to swing toward and from said stop-face, and to bear against the other side of said rail; and means effective to automatically swing said dog.

10. In a window-bracket, the combination of stanchions; a frame secured thereto; an adjustable stop-face carried by the frame, and adapted to bear against one side of a cash-rail; a dog pivoted to swing toward and from said stop-face, and to bear against the other side of said rail; and means effective to normally and automatically swing said dog away from said stop-face and upon the entry of the cash-rail between said dog and stop-face to swing said dog toward said rail.

11. In a window-bracket, the combination of stanchions; a frame secured thereto; a stop-face carried by the frame, and adapted to bear against one side of a cash-rail; a dog pivoted to swing toward and from said stop-face, and to bear against the other side of said rail; and means, said stop-face, and to bear against the other side of said rail; and means,

comprising a weighted arm, effective to normally and automatically swing said dog away from said stop-face and upon the entry of the mesh-rail between said dog and stop-face to swing said dog toward said rail.

12. In a window-bracket, the combination of stanchions; a frame secured thereto; an adjustable stop-face carried by the frame, and adapted to bear against one side of a mesh-rail; a dog pivoted to swing toward and from said stop-face, and to bear against the other side of said rail; and means, comprising a weighted arm, effective to normally and automatically swing said dog away from said stop-face and upon the entry of the mesh-rail between said dog and stop-face to swing said dog toward said rail; and a stop supported by the stanchions.

13. In a window-bracket, the combination of stanchions; a frame secured thereto; an adjustable stop-face carried by the frame, and adapted to bear against one side of a mesh-rail; a dog pivoted to swing toward and from said stop-face, and to bear against the other side of said rail; and means, comprising a weighted arm, effective to normally and automatically swing said dog away from said stop-face and upon the entry of the mesh-rail between said dog and stop-face to swing said dog toward said rail; and a stop adjustably supported by the stanchions.

14. In a window-bracket, the combination of stanchions; frames secured to the top thereof; a stop-face carried by each frame and adapted to bear against one side of a mesh-rail; a dog pivoted to swing toward and from said stop-face and to bear against the other side of said rail; means effective to normally and automatically swing said dog away from said stop-face, and upon the entry of the mesh-rail between said dog and stop-face to swing said dog toward said rail; brackets secured to the bottoms of said stanchions and comprising portions effective to engage the side and bottom of the lower rail of a mesh; and a portion effective to engage the stop on the lower portion of a window-frame.

15. In a window-bracket, the combination of stanchions; frames secured to the top thereof; a stop-face carried by each frame and adapted to bear against one side of a mesh-rail; a dog pivoted to swing toward and from said stop-face and to bear against the other side of said rail; means effective to normally and automatically swing said dog away from said stop-face, and upon the entry of the mesh-rail between said dog and stop-face to swing said dog toward said rail; brackets secured to the bottoms of said stanchions and comprising portions effective to engage the side and bottom of the lower rail of a mesh; and a portion effective to engage the stop on the lower portion of a window-frame; and a stop carried by said stanchions.

16. In a window-bracket, the combination of stanchions; frames secured to the top thereof; an adjustable stop-face carried by each frame and adapted to bear against one side of the upper rail of a mesh; a dog pivoted to swing toward and from said stop-face and to bear against the other side of said rail; means comprising a weighted arm effective to normally and automatically swing said dog away from said stop-face, and upon the entry of the mesh-rail between said dog and stop-face to swing said dog toward said rail; brackets secured to the lower ends of each stanchion and comprising means for adjustably securing said bracket thereto, a portion effective to engage the side and bottom of the lower rail of a mesh, a portion effective to engage the stop on the lower portion of a window-frame, and a ledge effective to support the stanchions; and a stop carried by each stanchion.

17. In a window-bracket, the combination of stanchions; frames secured to the top thereof; an adjustable stop-face carried by each frame and adapted to bear against one side of the upper rail of a mesh; a dog pivoted to swing toward and from said stop-face and to bear against the other side of said rail; means comprising a weighted arm effective to normally and automatically swing said dog away from said stop-face, and upon the entry of the mesh-rail between said dog and stop-face to swing said dog toward said rail; brackets secured to the lower ends of each stanchion and comprising means for adjustably securing said bracket thereto, a portion effective to engage the side and bottom of the lower rail of a mesh, a portion effective to engage the stop on the lower portion of a window-frame and a ledge effective to support the stanchions; and a stop adjustably carried by each stanchion.

18. In a window-bracket, the combination of stanchions; frames secured to the top thereof; an adjustable stop-face carried by each frame and adapted to bear against one side of the upper rail of a mesh; a dog pivoted to swing toward and from said stop-face and to bear against the other side of said rail; means comprising a weighted arm effective to normally and automatically swing said dog away from said stop-face, and upon the entry of the mesh-rail between said dog and stop-face to swing said dog toward said rail; brackets secured to the lower ends of each stanchion and comprising means for adjustably securing said bracket thereto, a portion effective to engage the side and bottom of the lower rail of a mesh, a portion effective to engage the stop on the lower portion of a window-frame; and a stop carried by said stanchions on the side of the window-frame on which said stanchions are supported.

19. In a window-bracket, the combination of stanchions; frames se-

secured to the top thereof; an adjustable stop-face carried by each frame and adapted to bear against one side of the upper rail of a mesh; a dog pivoted to swing toward and from said stop-face and to bear against the other side of said rail; means comprising a weighted arm effective to normally and automatically swing said dog away from said stop-face, and upon the entry of the mesh-rail between said dog and stop-face to swing said dog toward said rail; brackets secured to the lower ends of each stanchion and comprising means for adjustably securing said bracket thereto, a portion effective to engage the side and bottom of the lower rail of a mesh, a portion effective to engage the stop on the lower portion of a window-frame; a stop carried by said stanchions on the side of the window-frame on which said stanchions are supported, and a swinging stop supported by said stanchions on the opposite side of the mesh.

20. In a window-bracket, the combination of stanchions; frames secured to the top thereof; an adjustable stop-face carried by each frame and adapted to bear against one side of the upper rail of a mesh; a dog pivoted to swing toward and from said stop-face and to bear against the other side of said rail; means comprising a weighted arm effective to normally and automatically swing said dog away from said stop-face, and upon the entry of the mesh-rail between said dog and stop-face to swing said dog toward said rail; brackets secured to the lower ends of each stanchion and comprising means for adjustably securing said bracket thereto, a portion effective to engage the side and bottom of the lower rail of a mesh, a portion effective to engage the stop on the lower portion of a window-frame; a stop carried by said stanchions on the side of the window-frame on which said stanchions are supported; and a pair of stops swingingly supported by said stanchions, one above said mesh and the other on the opposite side from said stanchions.

21. In a window-bracket, the combination with stanchions carrying a stop, of self-clamping means for supporting said stanchions on the mesh.

22. In a window-bracket, the combination with stanchions carrying stops, of self-clamping means for supporting said stanchions on the mesh, said means comprising a stop-face carried by a frame and adapted to bear against one side of the top rail; a dog pivoted to swing from said stop-face and to automatically clamp against the other side of said top rail, and means bearing on the side and under side of the lower rail of the mesh.

23. In a window-bracket, the combination with stanchions carrying stops, of self-clamping means for supporting said stanchions on the mesh, said means comprising a stop-face carried by a frame and adapted to bear against one side of the top rail; a dog pivoted to swing from said stop-face and to automatically clamp against the other side of said top rail, and means bearing on the side and under side of the lower rail of the mesh.

24. In a window-bracket, the combination of stanchions carrying a stop; means for supporting said stanchions upon the upper rail of a window-frame; means for supporting the lower portion of said stanchions and comprising a bracket embodying a portion effective to engage the side and bottom of the lower rail of a window-frame, and a portion effective to engage the stop on the lower portion of a window-frame.

25. In a window-bracket, the combination of stanchions carrying a stop; means for supporting said stanchions upon the upper rail of a window-frame; means for supporting the lower portion of said stanchions and comprising a bracket embodying a portion effective to engage the side and bottom of the lower rail of a window-frame and a portion effective to engage the stop on the lower portion of a window-frame; and a ledge effective to support the stanchions.

26. A bracket comprising a clamp for securing the same to a stanchion; portions to engage the side and bottom of the lower rail of a window-frame; and a portion to engage the stop on the lower portion of a window-frame.

27. A bracket comprising a clamp for securing the same to a stanchion; portions to engage the side and bottom of the lower rail of a window-frame; a portion to engage the stop on the lower portion of a window-frame; and a ledge to support said stanchion.

28. In a window-bracket, the combination of a stanchion; means for clamping said stanchion upon the upper rail of a window-frame, and means for engaging the lower portion of the mesh, the organization being such that the engagement with the lower portion of the mesh is effective to maintain the clamping device in engagement with the upper rail.

29. In a window attachment the combination of a stanchion, means at the upper end to catch the upper rail of a window, means for supporting a lower portion of said stanchion comprising a bracket and body, and a portion effective to engage the mesh bracket to the lower rail of the mesh.

30. The combination with upright stanchions adapted to be supported upon window-frame, of automatic means for engaging and clamping the upper ends of said stanchions to the top rail of the mesh, and means for supporting the lower portion of said stanchions upon the mesh.

31. In a window-bracket, the combination with an upright stanchion, of means carried by the lower portion of said stanchion for engaging the window-frame on the under side of the lower rail of the mesh, means for automatically engaging and clamping upon the upper rail of said mesh and

effective to support the upper end of said stanchion, said means being adjustable upon the stanchion.

32. A window-bracket comprising a stop, supporting means for said stop, means for engaging and clamping the same automatically to the upper rail of a mesh, and means for maintaining the same adjacent to the lower rail thereof.

33. In a bracket the combination of a stanchion supporting means for the upper end of said stanchion embodying an automatic clamp for engaging the rail, means for supporting the lower portion of said stanchion and embodying a bracket effective when in position to secure and lock the clamping means.

34. A window attachment comprising a supporting means having an automatic clamp to catch over the upper rail of a window-frame; means for maintaining the supporting means adjacent to the lower rail thereof; and a stop carried by the supporting means.

35. A window attachment comprising a supporting means having an automatic clamp to catch over the upper rail of a window-frame, and means to catch the under side of the lower rail thereof, and a pair of stops carried by the supporting means.

36. A window attachment comprising a supporting means; means for catching the same upon the upper rail of a mesh; means for catching the same upon the lower rail thereof; and a swinging stop carried by the supporting means.

37. A window attachment, comprising a supporting means; means for catching it upon the upper rail of a mesh; means for catching the lower rail thereof for maintaining the same adjacent to the mesh and for maintaining the device upon the side of the mesh upon which said supporting means is located, and one of which stops swings from each support side of the mesh to the side of the mesh remote therefrom.

38. A window-bracket embodying means effective to engage the top rail of a mesh; means adapted to slide under and engage the lower rail thereof and thereby effective to lock the top-rail-engaging means upon the mesh; and means effective to hold the lower-rail-engaging means in place.

698,768. SAFETY-CLAMP. JAMES TUCKER, Worcester, Mass. Filed Feb. 27, 1902. Serial No. 25,908. (No model.)

Claim.—In a safety-clamp, the combination with a frame, as a, provided with arms, as b, having slots b' and b'', of a mesh or guard c provided with ears f, and arms g, the latter having outwardly bent legs h to enter the slots b' and b'', and extend over i passing through the slots b' and b'' and tapped in the mesh c.

698,764. FRUSTRING-SAW. GEORGE E. TYLER, Panama, Cal. Filed Aug. 13, 1901. Serial No. 71,908. (No model.)

Claim.—1. A pruning-saw comprising a handle having its head and grip slotted, reinforcing-plates secured on each side of the slotted portion of the handle and under the butt thereof, a reinforcing-plate secured to the head and having its front portion slotted and its upper portion undotted to constitute a stop, and a saw pivotally mounted between the slotted portion of the head and engaging the stop when in operative position,

the saw being designed to close in between the slotted portion of the grip to permit of the implement being carried on the person of the user, substantially as described.

2. A pruning-saw comprising a curved handle having its head and grip slotted, reinforcing-plates secured on each side of the slotted portion of the handle and under the butt thereof, a reinforcing-plate secured to the head and having its front portion slotted and its upper portion undotted to constitute a stop, and a curved saw pivotally mounted between the slotted portion of the head and engaging the stop when in operative position, the saw being designed to close in between the slotted portion of the grip, substantially as described.

698,765. PIPE-WRENCH. ALFRED WUNDERMAN, St. City, Pa. Assignor to GE. Wolf Supply Company, Pittsburgh, Pa., a Corporation of Pennsylvania. Filed Feb. 5, 1902. Serial No. 25,909. (No model.)

Claim.—1. A pipe-tongs jaw having a bit or die-block pocket, constructed to substantially surround the bit or die-block, and a spring-detent arranged at the mouth of said pocket, substantially as and for the purposes specified.

2. A pipe-tongs jaw having a bit or die-block pocket constructed to substantially surround the bit or die-block, and a leaf-spring detent or keeper arranged at the mouth of said pocket, substantially as specified.

3. A pipe-tongs jaw having a bit or die-block pocket, a leaf-spring detent or keeper arranged at the mouth of said pocket, and a clearance-slot which communicates with the mouth of the leaf-spring detent, substantially as and for the purposes specified.

698,766. PROCESS OF MANUFACTURING GLASS. ALFRED VOLLMER, Brunswick, Germany. Filed Sept. 27, 1900. Serial No. 21,211. (No specimens.)

Claim.—A process of manufacturing glass by electrical heating which consists in first melting the raw materials in the electric arc and then passing on electric current through the crude molten glass each current being sufficiently strong to heat the molten glass to a temperature at which entrapped gas-bubbles can readily escape from it, substantially as described.

698,767. GUM-MAKING MACHINE. GEORGE E. WILSON, and EDWARD J. BARNES, Chicago, Ill. Filed Dec. 5, 1901. Serial No. 84,798. (No model.)

Claim.—In a gum-making machine in combination, a cylindrical casing in open communication with a hopper, a die attached to the outlet of

angle to the slots when the parts are in operative position and adapted to be brought in alignment with the slots to assemble the parts, and means for actuating the movable member, substantially as described.

3. A snap-ringer comprising stationary and movable members, a shaft journaled on one of the members, parallel flanges mounted on the other member, one of the flanges being provided with a bearing-opening and the other flange having a bearing-socket, an arm having pivots arranged in the bearing-opening and in the bearing-socket, said arm projecting between the flanges when the parts are in operative position, and having a cut-away portion adapted to be arranged adjacent to the flange having the bearing-socket, whereby the parts may be readily assembled, and means for connecting the arm with the shaft, substantially as described.

4. A snap-ringer comprising stationary and movable members hinged together, the movable member being provided at opposite sides with parallel flanges arranged in pairs, one of the flanges being provided with an opening and the other having a bearing-socket, ball-crank arms provided with oppositely-disposed pivots arranged in the openings and sockets of the flanges, a rock-shaft journaled on the stationary member, and links connecting the ball-crank arms with the rock-shaft, substantially as described.

698,774. MATCH-SAFE. STEPHEN L. WHITEHEAD, Boston, Va. Filed Jan. 27, 1902. Serial No. 91,404. (No model.)

Claim.—1. In a match-safe having an inclined chute, a curved pick-up and delivery-arm, a lever for operating said arm, and a detacher located in the path of the free end of the said arm, substantially as set forth.

2. In a match-safe, a spring pivoted arm for picking up and delivering the matches, a detacher located in the path of the free end of the said arm, and means for operating the arm, substantially as specified.

3. In a match-safe having a delivery-slot, an inclined chute, a detacher, and a pivoted spring-arm having a coil intermediate of its ends and adapted to pick up a match and deliver the same upon the inclined chute, substantially as set forth.

698,775. AUTOMOBILE LOW-WATER ALARM FOR AUTOMOBILES. TANKER GEORGE R. WHITNEY, Boston, Mass., assignor to Whitney Motor Wagon Company, Elkhart, Ind., a Corporation of Indiana. Filed June 22, 1901. Serial No. 65,576. (No model.)

Claim.—1. In a motor-vehicle a low-water audible-alarm device arranged within a water vessel.

2. In a motor-vehicle a low-water audible-alarm device contained in the water-tank thereof and normally, wholly or partially submerged in the water contained in said water-tank.

3. A low-water alarm for motor-vehicles consisting of a sounding member normally submerged in the water and means to strike the same.

4. In a motor-vehicle, a low-water alarm consisting of a continuously-operating alarm device arranged within the tank, the contained water when partially or wholly submerging the said device operating to prevent its audible sounding.

5. In a motor-vehicle a low-water alarm device consisting of a bell, gong or other vibratory member and one or more gravity-actuated switches therefor, the whole being partially or wholly submerged within the water-tank.

6. A low-water alarm for motor-vehicles comprising a bell, gong or other vibratory member and one or more rolling strikers all arranged within the water-tank and to be partially or wholly submerged in the water therein.

7. In a motor-vehicle an audible low-water alarm consisting of a submerged bell, gong or other vibratory member, one or more strikers therefor, and resilient holders interposed between said strikers and said bell, gong or member and normally holding said strikers out of operative contact therewith.

8. In a motor-vehicle an audible low-water alarm consisting of a submerged bell, gong or other vibratory member, one or more strikers therefor, and means to hold the said strikers out of contact with the said bell, gong or member, the said strikers in their striking movements overcoming said holding means temporarily in delivering the blow upon the bell.

9. In a motor-vehicle an audible low-water alarm device containing a submerged bell, gong or other cup-shaped member having its crown upturned, with means to permit the escape of air from within the same.

10. In a motor-vehicle an audible low-water alarm device containing a submerged bell, gong or other cup-shaped member, the same being perforated to permit escape of contained air.

698,776. FRUIT BOX OR BASKET. GEORGE R. WHITNEY, Toronto, Canada. Filed Dec. 11, 1901. Serial No. 85,682. (No model.)

Claim.—1. A fruit-box comprising the bottom and two opposite sides having central vertical slots and the two remaining sides having tongues narrowed at the outer end and provided with hooks designed to be inserted through the slots, so as to hold the sides in a substantially upright position and form pockets on the outside one on each side of the slots and an independent cover provided with end flaps and side depending tongues fitting into said pockets on each side of the slots as and for the purpose specified.

2. In an article such as described, the combination with the basket and the cover thereof and the narrow ball having wide flattened ends, of one formed with a narrow central opening and centrally secured to the tops of the sides and provided with depending portions, said depending portions being designed to be bent inward to hold said ball in position, substantially as described.

3. A fruit-box comprising the bottom and two opposite sides having central vertical slots and the two remaining sides having tongues narrowed at the outer end and provided with hooks designed to be inserted through the slots, so as to hold the sides in a substantially upright position and the one formed with a central opening and suitably secured to the tops of the sides and provided with depending portions and the ball extending through the openings in the sides and provided with flattened ends designed to be held in position by each depending portion as and for the purpose specified.

698,777. WOVEN ELASTIC FABRIC AND METHOD OF MAKING SAME. ALFRED H. EDELMAN, Boston, Mass. Filed July 1, 1901. Serial No. 66,005. (No model.)

Claim.—1. An elastic fabric presenting at intervals straight parallel selvages, and at intervals cleaved and concaved selvages, to thereby prevent cracks in the fabric.

2. An elastic fabric composed of elastic warp, a binder-warp, and filling, the filling at predetermined points in the weaving extending lat-

partially through the fabric in the direction of its width to thereby provide for a wrack in the fabric when the elastic warp is released from tension.

3. The herein described method of weaving elastic fabric which consists in stretching the elastic warp, forming sheds in the binder-warp between said elastic warp, and inserting the filling at intervals through the sheds of a portion only of the binder-warp-thread, returning the filling about elastic warp-threads intermediate the warp-threads constituting the selvages of the fabric, the contraction of the elastic warp causing that edge of the fabric through which the filling does not extend to the selvage-warp, to present a concaved appearance.

698,778. SHEDDING AND FLANNING MACHINES. BENJAMIN B. BISHOPMAN, Buenos Ayres, Argentina. Filed May 4, 1901. Serial No. 66,764. (No model.)

Claim.—1. In combination, the draft-beam, a member pivoted thereto, shown rigidly connected to the member to tilt therewith and means for tilting the member in relation to the beam, substantially as described.

2. In combination, the draft-beam, a member pivoted thereto, shown rigidly connected to the member to tilt therewith and means for tilting the member in relation to the beam, said means comprising a lever pivoted to the beam, a segment on the beam for holding the lever in any desired position, and a strap connecting the lever with the member, substantially as described.

3. In combination, a member, a feed-slide therein, a block carried by said feed-slide and adjustable from the upper to the lower side thereof, said block being also adjusted in a direction longitudinally of the slide and a wheel carrying two rows of teeth, said teeth operating transversely of the end of the feed-slide and being located at the end of the member, substantially as described.

698,779. CHAIN WRENCH. GEORGE ANDERSON, JR., Brooklyn, N. Y., assignor to J. E. Williams and Company, Brooklyn, N. Y., a Corporation of New York. Filed July 22, 1901. Serial No. 66,514. (No model.)

Claim.—1. A chain wrench having, in combination, a handle with chain-carrying recesses in the opposite faces; a head with opposite grip-faces in line with the faces of the handle, said head being composed of two like sections which at their bases embrace the end of said handle at the sides, said head-sections being recessed and shouldered on their facing surfaces to fit the end of the handle, the outer ends of said head-sections meeting beyond the end of the handle so as to provide substantially continuous gripping-surfaces on each face; means for securing the head-sections to the handle; a chain pivotally connected near their common apex with pin-receiving recesses closed at their ends but communicating with an open-mouthed slot extending to the apex of the head; means for securing the head-sections to the handle; a pivot-pin located in said pin-receiving recesses, and retained in place by the assembly of the head-sections to the handle; a screwable flat chain pivotally connected to the said pivot-pin and symmetrically disposed with reference to a longitudinal plane extending medially through the handle and the grip-faces, said chain having laterally-projecting locking-pieces; and locking provisions on said head-sections near the base thereof and on both faces of the wrench, said locking provisions cooperating with said chain-studs, and being constructed so as to prevent the chain becoming accidentally detached when in use.

2. A chain wrench having, in combination, a handle; a head with opposite grip-faces, said head being composed of two sections which at their bases embrace the end of said handle at the sides, the outer ends of said head-sections meeting beyond the end of the handle so as to provide substantially continuous gripping-surfaces on each face; means for securing the head-sections to the handle; a chain pivotally connected at the apex of said head; and locking provisions for said chain near the base of said head.

3. A chain wrench having, in combination, a handle; a head composed of two sections which at their bases embrace the end of said handle at the sides, the outer ends of said head-sections meeting beyond the end of the handle, and said sections being formed near their common apex with pin-receiving recesses closed at their ends but communicating with an open-mouthed slot extending to the apex of the head; means for securing the head-sections to the handle; a pivot-pin located in said pin-receiving recesses, and retained in place by the assembly of the head-sections to the handle; a chain pivotally connected to the said pivot-pin; and locking provisions for said chain near the base of said head.

4. A chain wrench having, in combination, a handle; a head composed of two sections which at their bases embrace the end of said handle at the sides, the outer ends of said head-sections meeting beyond the end of the handle, and said sections being formed near their common apex with pin-receiving recesses closed at their ends but communicating with an open-mouthed slot extending to the apex of the head; means for securing the head-sections to the handle; a pivot-pin located in said pin-receiving recesses, and retained in place by the assembly of the head-sections to the handle; a chain pivotally connected to the said pivot-pin; and locking provisions for said chain near the base of said head.

5. A chain wrench having, in combination, a handle; a head with opposite grip-faces in line with faces of the handle, said head being composed of two sections which at their bases embrace the end of said handle at the sides, said head-sections being recessed and shouldered on their facing surfaces to fit the end of the handle, the outer ends of said head-sections meeting beyond the end of the handle so as to provide substantially continuous gripping-surfaces on each face; means for securing the head-sections to the handle; a pivotally-connected chain; and locking provisions for the chain.

6. A chain wrench having, in combination, a handle; a head composed of two sections which at their bases embrace the end of said handle at the sides, the outer ends of said head-sections meeting beyond the end of the handle; means for securing the head-sections to the handle; a pivotally-connected chain; and locking provisions for said chain.

7. A chain wrench having, in combination, a handle; a head with opposite grip-faces extending across the plane of the handle, each grip-face extending on both sides of a plane passing centrally and longitudinally through the handle, said head comprising a section which at its base ends upon the end of said handle at its side, the outer end of said head-section extending beyond the end of and in line with the handle; means for securing the head to the handle; a pivotally-connected chain opposed in said head and having, when in use, a fixed definite pivotal point; and locking provisions for said chain.

8. A convertible chain wrench having, in combination, a handle, a two-part detachable united head with opposite grip-faces extending across the plane of the handle, means for securing said head to said handle, and a chain, said head being constructed with pin-receiving recesses near its apex and also near its base, adapted to receive and maintain in fixed definite position a pivot-pin for the attachment of the chain, said recesses being accessible for the reception of the pivot-pin and the chain when the head-sections are detached from the handle, and said pivot-pin and chain being retained in place by the assembly of the handle and head.

sections, and said chain and head being opposed to each other so that when in use they embrace squarely between them the article to be turned.

9. A convertible chain wrench having, in combination, a handle, a control head with opposite grip-faces extending across the plane of the handle and a chain, said wrench being constructed with means near the open end and also near the base of the head to receive and retain in fixed definite position a pivot-pin for the attachment of the chain, said chain and head being opposed to each other so that when in use they embrace squarely between them the article to be turned.

10. A chain wrench having, in combination, a handle, a head, locking provisions on opposite faces of the wrench, and a reversible chain, adapted to engage with the locking provision on either face, said chain being pivotally connected to the head so as to swing over the head in both directions by means of a pivot having a fixed definite constant location at one side of a longitudinal plane passing through the apex of the head and midway between the said locking provisions on opposite faces of the wrench, whereby fine adjustment of the chain is opened.

698,780. CHAIN PIPE-WRENCH. GEORGE ANDERSON, JR., Brooklyn, N. Y., assignor to J. H. Williams and Company, Brooklyn, N. Y., a Corporation of New York. Filed July 27, 1901. Serial No. 68,910. (No model.)

Claim.—1. A chain pipe-wrench having a handle, a head, the head and the handle being so related to each other as to leave an open-sided chain-receiving passage between said head and handle, a chain attached to the head and adapted to be passed through said passage, and locks behind said passage to engage said chain.

2. A chain pipe-wrench having, in combination, a handle, a head, a chain-receiving passage, a chain pivotally connected to the head at or near its apex and adapted to be passed through said passage, and locks to engage said chain behind said passage.

3. A chain pipe-wrench having, in combination, a handle, a head secured to one side of said handle and having opposite grip-faces substantially in line with the faces of the handle, said head extending beyond the end of the handle so as to provide an open-sided chain-receiving passage, locks on both faces of the wrench behind said passage, and a reversible flat chain pivotally connected to the head at or near the apex and adapted to be passed through said passage in either direction and locked by one end of said chain, or to be locked on either face of the wrench without being passed through said passage.

4. A chain pipe-wrench having, in combination, a handle, a head secured to one side of said handle and having opposite grip-faces substantially in line with the faces of the handle, said head extending beyond the end of the handle so as to provide an open-sided chain-receiving passage, locks on both faces of the wrench, and a reversible flat chain pivotally connected to the head at or near the apex and adapted to be passed through said passage in either direction and locked by one end of said chain, or to be locked on either face of the wrench without being passed through said passage.

5. A chain pipe-wrench having, in combination, a handle, a head secured to one side of said handle and having opposite grip-faces substantially in line with the faces of the handle, said head extending beyond the end of the handle so as to provide an open-sided chain-receiving passage, locks on both faces of the wrench, and a reversible chain pivotally connected to the head at or near the apex and adapted to be passed through said passage in either direction and locked by one end of said chain, or to be locked on either face of the wrench without being passed through said passage.

698,781. PERMUTATION-LOCK. JOHN W. ANDERSON and GEORGE H. ANDERSON, Weymouth, Pa., assignors to the Kayless Lock Company, Lehigh, Pa., a Corporation of Delaware. Filed Apr. 8, 1901. Serial No. 68,101. (No model.)

Claim.—1. In a permutation-lock, the combination with a suitable lock-case; a spindle mounted therein; a reciprocating bolt provided with a yoke-shaped slot through which the spindle projects; a bifurcated plate straddling the spindle and adapted to engage the bolt; a face on said plate, a flange projecting laterally from one arm of the plate to engage a projection of the casing, a plurality of notched disk-shaped tumblers on the spindle designed to engage the face when the notches align; and means carried by the spindle for retracting said bolt when the combination is moved.

2. In a permutation-lock, the combination with a case; of a spindle mounted therein; a plurality of notched tumblers mounted on said spindle and adapted to align with each other; a sliding bolt in the case having a slot through which a spindle projects; a laterally-projecting arm on said bolt; a bifurcated plate straddling the spindle; a leg or projection on said plate for engagement with the arm; a face carried by the plate and adapted to engage the notches in the tumblers whereby the bolt can be retracted by a partial rotation of said tumblers.

3. In a permutation-lock, the combination with a case; of a spindle mounted therein; a plurality of notched tumblers mounted on said spindle and adapted to align with each other; a sliding bolt in the case having a slot through which a spindle projects; a laterally-projecting arm on said bolt; a bifurcated plate straddling the spindle; a leg or projection on said plate for engagement with the arm; a face carried by the plate; and adapted to engage the notches in the tumblers whereby the bolt can be retracted by a partial rotation of said tumblers; and means for withdrawing said lever from engagement with the notches comprising a laterally-projecting foot on the plate and a pin projecting from the casing to engage said foot.

698,782. ANIMAL CRATE. RICHARD E. BAKER, Detroit, Mich. Filed May 18, 1900. Serial No. 717,342. (No model.)

Claim.—1. An article of manufacture, comprising an animal-crate having a wall of horizontal slats placed edge to edge forming a solid bottom, or lower portion of said wall, but spaced at the top to form horizontal ventilating openings, straight transverse wires passing the exterior of said slats, metal guards embracing the edges and extending into the sides of the slats bordering said ventilating openings, binding-wires embracing said slats and wound around said transverse wires between the spaced slats so as to become interposed between the metal guards for confining said guards to said slats and maintaining the slats properly spaced.

2. An article of manufacture comprising an animal-crate, having a wall of slats placed edge to edge to form a solid portion at the bottom of said wall but spaced at the top of the wall to form ventilating openings, transverse struts crossing said slats, metal guards embracing the edges and extending into the sides of the slats bordering the ventilating openings, binding-strands embracing said slats and said metal guards to bind them together, spacing members interposed between the metal guards at the ventilating openings to confine the guards in position and to properly space the slats to form said openings.

698,783. CULTIVATOR. JOHN R. BALDWIN, Detroit, Mich. Filed Feb. 26, 1901. Serial No. 68,004. (No model.)

Claim.—1. In a cultivator, the combination of the main frame, rocking supports therefor at the rear and forward portions thereof respectively, and means for simultaneously rocking said supports to vary the position of the frame thereon.

2. In a cultivator, the combination with the main frame, of the

rocked axle pivoted to the rear thereof, the plow and the beams therefor, a rocking support for the forward frame and extending from the latter to the plow-beams and movable in unison with the rocked axle, and means for shifting the frame.

3. In a cultivator, the combination with the main frame, of the rocked axle pivoted to the rear thereof, the plow and plow-beams, an arched supporting-frame pivoted to the forward frame and end to the forward ends of the beams, and means for rocking the axle and arched frame simultaneously.

4. In a cultivator, the combination with the frame, of the wheeled axle pivoted thereto, an arched lever fixedly secured to the axle, means for locking said lever in different positions of adjustment, the plow, and connections between said plow and the lever.

5. In a cultivator, the combination with the frame, of the wheeled axle pivoted thereto, an arched lever fixedly secured at its ends to the axle, gear-segments secured to said lever, labels carried by the standard adapted to engage the segments, the plow, and links connecting the plow and standards.

698,784. CAR-BRAKE. ARTHUR BALON, Elizabeth, N. J. Filed Nov. 1, 1901. Serial No. 68,781. (No model.)

Claim.—A car-brake provided with a bearing, an upper and a lower pin received thereby and projecting with their ends beyond the bearing, spring-influenced perforated brake-choes adapted to slide upon the projecting ends of the pins, and an eccentric that engages the brake-choes intermediate the pins, substantially as specified.

698,785. AUTOMATIC FIREPROOF DOOR. DR. CHARLES A. BALDWIN, Montreal, Canada. Filed June 28, 1901. Serial No. 68,000. (No model.)

Claim.—1. In an automatic fireproof door, the combination with a frame having two independent sets of guide-grooves, of a plurality of door-sections slidably mounted in each of said sets of guide-grooves, a plate mounted upon the lower edge of each of the inner door-sections, each of said plates overlapping the lower edge of the adjacent outer door-section, a locking-bolt secured to each of the innermost door-sections and projecting inwardly therefrom, a bracket mounted upon a

substantially portion of the framework and adapted to receive each of the said locking-bolts, and a face mounted in said bracket and adapted to retain the locking-bolts in their normal position, substantially as shown and described.

2. In an automatic fireproof closing device, the combination with a frame, door-sections slidably mounted in said frame, a flange plate, and a hinged lever having its end supported by said flange plate and adapted to retain the said door-sections in their raised position, whereby the raising of the said plate will release said door-sections, substantially as shown and described.

3. In an automatic fireproof closing device the combination with a window frame and sashes, of an auxiliary frame applied to said window-frame, door-sections slidably mounted in said auxiliary frame, a flange plate, and a hinged lever having its end supported by said flange plate and adapted to retain the said door-sections in their raised position, whereby the raising of the said plate will release said door-sections and form a dead-air chamber between said door-sections and said window-sashes, substantially as shown and described.

4. In an automatic fireproof closing device, the combination with a frame provided with suitable guide-grooves, door-sections slidably mounted in said frame, a plate adjustably mounted upon each of said door-sections, and a projecting leg integral with said plate and adapted to engage and slide in said guide-grooves, substantially as shown and described.

5. In an automatic fireproof closing device, the combination with a frame provided with suitable guide-grooves, door-sections slidably mounted in said frame, a plate adjustably mounted upon each of said sections, a projecting hollow leg integral with said plate and adapted to engage and slide in said guide-grooves, and friction-rollers mounted in said leg, substantially as shown and described.

6. In an automatic fireproof closing device, the combination with a frame, of a door-section slidably mounted in said frame, having a groove in its upper edge, a perforated plate removably clamped upon the upper edge of said door-section and over said groove, a wire rope having its lower end passed through the perforation in said plate and clamped with in said groove, substantially as shown and described.

698,786. SANITARY SPUTTOOK. HAROLD J. BRADSHAW and HAROLD J. TRIMMER, Worcester, Mass.; said Bradshaw assignor to said Trimmer. Filed Aug. 8, 1901. Serial No. 71,308. (No model.)

Claim.—1. As an article of manufacture, a sputtook comprising a floor-plate having an annular distributing-groove on its under side, a water-pipe connected substantially tangentially to the distributing-groove, and a sheet-metal body portion secured to the floor-plate so as to have a narrow discharge-opening between the sheet-metal body portion and the inner edge of the distributing-groove, whereby a spiral discharge of water will be caused over the entire inner surface of the body portion from its upper edge downward.

2. As an article of manufacture, a sputtook comprising a floor-plate 10 adapted to be set into and covered by a grate 12 in place in a floor, and having a supporting-ledge 11 for detachably receiving a grating 13, and having on its under side an annular distributing-groove, a supply-pipe 14 connected to the distributing-groove, and a sheet-metal body portion secured to the floor-plate so as to have a narrow discharge-opening between the body portion and the inner edge of the distributing-groove, so that the entire inner surface of the body portion from its upper edge down will be flushed by the discharge of water from the distributing-groove, and a fitting 16 connected with the lower end of the body portion, and having a return-bend forming a trap, substantially as described.

698,787. WHEEL-CONVERTER. SAMUEL K. SUMMERS, Washington, D. C., assignor to Howard Evans, Philadelphia, Pa. Filed July 31, 1900. Serial No. 55,694. (No model.)

Claim.—1. A converter comprising a stationary shaft, and a movable ball, the ball adapted to enclose the shaft, and the shaft having a series of tryons extending around it, their lower ends extend-

ing no lower than the upper end of the ladle whereby the blast of air issuing from the tuyere is directed upon the surface of the metal and toward the center thereof.

2. A converter comprising a stack and ladle, one stationary and the other movable, the ladle adapted to contain the molten metal and the stack having a plurality of tuyeres therein which extend around it at a point at or near its lower end and no lower than the upper edge of the ladle, said tuyeres vertically adjustable and constructed and adapted to be locked in any of their various adjustments.

3. A converter comprising a stack and ladle, one of which is movable with respect to the other, the stack having tuyeres located at its lower end, which tuyeres extend around the converter and are locked so lower than the upper edge of the ladle, said tuyeres being movable at their outer ends from their inner ends as centers and provided with means for locking them in the different adjustments.

4. A converter comprising a stack and ladle, one being stationary and the other movable, the ladle adapted to contain molten metal and the stack having a series of tuyeres extending entirely around it at a point at or near its lower end, the stack also provided at its lower end with openings for the removal of slag therefrom, the inner ends of the tuyeres and the slag-openings being in approximately the same horizontal plane.

5. A converter comprising a stack and ladle detachably connected together, a wind-supply and a series of tuyeres in communication with said wind-supply and extending around the converter with their discharge ends at a level approximately coincident with the joint formed between the stack and ladle.

6. The combination with the stack, of a truck carrying a ladle which latter forms the complement of the stack when in contact therewith, the truck having a centrally-located socket on its lower surface, a block below the socket, said block having curved ways on its lower lateral surfaces, a shaft having a cone, said cone carrying antifriction-rollers adapted to turn in contact with the curved ways on said block, a worm-engagement on the shaft and a worm engaging said segment for rotating the shaft whereby to raise or lower the ladle of the converter.

7. The combination with the stack of a converter, of a truck having a ladle thereon, the truck having a centrally-located socket on its lower surface, a vertically-sliding block centrally located beneath the truck and in alignment with the socket when the truck is in position to be raised and lowered, and a rock-shaft having cone mechanism thereon constructed and adapted to raise and lower the block whereby to control the position of the truck.

698,788. BRAKE-BEAM. ARTHUR B. BELLON, Pittsburgh, Pa. Filed Sept. 27, 1901. Serial No. 76,702. (No model.)

Claim.—1. A brake-beam consisting of a flanged shape having parts of its web cut and bent outwardly to form flanges; substantially as described.

2. A brake-beam consisting of a rolled channel having openings cut between the center and its ends, and web portions cut and bent outwardly between the openings and the ends, the outwardly-bent portions forming flanges which are riveted together in pairs; substantially as described.

3. A channel-section having openings formed at each side of the center and web portions cut and bent in a direction opposite to the channel-flanges, forming flanges which are riveted together; substantially as described.

4. A brake-beam formed of a rolled section, the central portion being of the original width of the rolled section and containing a slot or hole, the ends of the beam being made narrower than the original width of the section, and a brake-rod, fulcrum or support arranged to receive a lever-bar extending through said hole; substantially as described.

5. A channel having intermediate parts of its web bent outwardly in a direction opposite to that of the channel-flanges, said bent portions being riveted together; substantially as described.

6. A brake-beam consisting of a channel having openings on opposite sides in its web, and web portions between said openings and its ends which are bent outwardly in a direction opposite to that of the channel-flanges, and brake-rod carriers secured by bolts extending through the channel-flanges; substantially as described.

698,789. CAR-DOOR MECHANISM. ARTHUR B. BELLON, Pittsburgh, Pa. Filed Dec. 28, 1901. Serial No. 80,022. (No model.)

Claim.—1. The combination with a car, having a longitudinal center rail, of twin doors arranged in pairs on each side of the rail and arranged to swing downwardly and outwardly, guides for the doors, a flexible loop extending between the guides, and a connection for raising and lowering the loop; substantially as described.

2. A car having two pairs of doors arranged on each side of the longitudinal rail, connecting bars or beams secured to corresponding doors of each pair, guides secured to the connecting-bars between the flange of the center rail, and an equalizing flexible loop extending through the guides; substantially as described.

3. A car having a pair of doors, upwardly-projecting guides symmetrically arranged on said doors, a chain loop having its opposite legs extending through said guides, and a flexible connection leading from the loop to a winding-drum; substantially as described.

698,790. LINING FOR BARRELS OR SIMILAR RECEPTACLES. FRANK L. BLANCHARD, New York, N. Y., assignor to the Arrol Safety Bag Company, New York, N. Y., a Corporation of New York. Filed June 12, 1902. Serial No. 20,897. (No model.)

Claim.—1. An expansible lining for barrels and similar receptacles, made of paper, and rendered elastic by crinkling or corrugating, and consisting of a body, and of a bottom united with the body by a curved seam which is substantially coincident with the contour of the bottom corner of the barrel to form a closed lining having a flat bottom.

2. As a new article of manufacture, a collapsible, elastic lining for barrels and similar receptacles, made of paper rendered elastic by crinkling or corrugating, and consisting of a body and of a flat closed bottom united with the body by a heavily-curved seam, which is substantially coincident with the contour of the bottom corner of the barrel or receptacle.

ling or corrugating, and consisting of a body and of a flat closed bottom united with the body by a heavily-curved seam, which is substantially coincident with the contour of the bottom corner of the barrel or receptacle.

698,791. GLASS-MACHINE. JOHN BROWN, Norwood, Mass., assignor to Louis C. Smith, Norwood, Mass. Filed Apr. 1, 1901. Serial No. 68,777. (No model.)

Claim.—1. In an apparatus of the class described, a support, a glass-receptacle detachably carried thereby, a hot-water jacket surrounding said receptacle, a distributing-roll, and a plurality of spreading-rolls mounted for rotation in said support, said rolls being independent of the glass-receptacle and forming the bottom thereof when said receptacle is in its operative position, a pair of pressure-rolls, an endless feed-roller having its free ends adjacent the distributing-roll, means to operate said pressure-rolls and feed-roller in unison, said rollers operating to feed sheets of material past said distributing-roll and also to feed the glass sheets and the backing to which they are to be applied to the said pressure-rolls, and a plurality of rigid clearing-fingers engaging the delivery side of said distributing-roll, and springs to yieldingly hold said fingers in contact with the said roll.

2. In an apparatus of the class described, a support, a glass-receptacle detachably carried thereby, a hot-water jacket surrounding said receptacle, a distributing-roll, and a plurality of spreading-rolls mounted for rotation in said support, said rolls being independent of the glass-receptacle and forming the bottom thereof when said receptacle is in its operative position, an endless feed-roller for feeding sheets of paper past said distributing-roll, means for driving said roller a series of pivotally-mounted clearing-fingers engaging the delivery side of said delivery-roll, springs to yieldingly hold said fingers in contact with the roll, and a substantially U-shaped scraper in said receptacle and bearing on the top of the distributing-roll, the upwardly-extended arm of said scraper being adjustably secured to the opposite side of the receptacle.

3. In an apparatus of the class described, a glass-receptacle, a hot-water jacket surrounding the same, a distributing and spreading roll forming the bottom of said receptacle, means to drive said roll, a pair of pressure-rolls, and an endless feed-roller adapted to feed sheets of material past said distributing-roll, and to feed the glass sheet and the backing to which it is to be applied to the pressure-rolls.

4. In an apparatus of the class described, a glass-receptacle, a water-jacket surrounding the same, burners located beneath said jacket, said jacket having wings pivoted to its lower edge, said wings operating to protect the flame of the burner, a distributing-roll and spreading-rolls forming the bottom of said receptacle, means to drive said rolls, and means to feed sheets of material to said distributing-roll.

5. In an apparatus of the class described, a glass-receptacle, an annular water-jacket surrounding the same, burners extending around the glass-receptacle and located beneath said jacket, wings pivoted to the lower edge of said jacket and protecting the burner, glass-distributing means, and means to feed the sheets of material to said glass-distributing means.

6. In an apparatus of the class described, a frame comprising a suitable platform having standards at one end, a glass-receptacle mounted on said standards, a distributing-roll and spreading-rolls rotatably mounted in said standards and forming the bottom of said glass-receptacle, a pair of pressure-rolls rotatably mounted at the other end of said platform, and a feed-roller adapted to feed sheets of material past the distributing-roll, and to feed the glass sheet, and the backing to which it is to be applied, to the pressure-rolls, said rollers being carried beneath the central portion of the platform, whereby the said central portion is accessible.

7. In an apparatus of the class described, a support, a distributing-roll, and spreading-rolls mounted for rotation therein, a glass-receptacle detachably carried on said support, said distributing and spreading rolls forming the bottom of said receptacle but being independent thereof, an annular hot-water jacket surrounding said receptacle, pressure-rolls, an endless feed-roller having the free ends thereof closely adjacent to the surface of the distributing-roll, said rollers operating to feed sheets of material past the distributing-roll, and the glass sheet and the backing to which they are to be applied to the pressure-rolls.

8. In an apparatus of the class described, a platform, a glass-distributing device at the side of said platform, a pair of pressure-rolls detachably mounted at the other end of said platform, and a feed-roller adapted to feed sheets of material past the glass-distributing device, and to feed the glass sheet and the backing to which it is to be applied to the pressure-rolls, said rollers being carried beneath the central portion of the platform, whereby the said central portion is accessible.

9. In an apparatus of the class described, a platform, a glass-distributing device at the side of said platform, a pair of pressure-rolls detachably mounted at the other end of said platform, and a feed-roller adapted to feed sheets of material past the glass-distributing device, and to feed the glass sheet and the backing to which it is to be applied to the pressure-rolls, said rollers being carried beneath the central portion of the platform, whereby the said central portion is accessible, combined with brushes for cleaning the feed-roller, said brushes being located beneath the central portion of the platform.

698,792. ARO-LIGHT HANGER-BEARD. IRVAN H. BUCK and WILLIAM H. SCHUPP, Baltimore, Md. Filed June 15, 1901. Serial No. 64,718. (No model.)

Claim.—1. An aro-light hanger-beard comprising a pair of counterbalance-levers, binding-posts on which the counterbalance-levers are pivoted and with which they are electrically connected, depending means whereby a lamp is supported by the counterbalance-levers, and electrically-connected contacts arranged in the paths of movement of the longer arms of the counterbalance-levers.

2. An aro-light hanger-beard comprising a pair of counterbalance-levers, circuit-wires, binding-posts on which the counterbalance-levers are pivoted and connected with the circuit-wires and electrically connected with the counterbalance-levers and contacts arranged in the paths of movement of the longer arms of the counterbalance-levers and with which the binding-posts are also electrically connected, and lamp-suspending means connected with the shorter arms of the counterbalance-levers in such a

manner as to normally hold the longer arms of the latter out of engagement with the contacts.

3. An arm-light hanger-board comprising circuit-wires, oppositely-located binding-posts for circuit-wires, oppositely-located counterbalance-levers fulcrumed on the binding-posts and electrically associated therewith, contacts arranged in the paths of movement of the longer arms of the counterbalance-levers when relieved of the weight of the lamp, short circuit-wires connecting the contacts with the binding-posts, and lamp-hanger rods connected with the shorter arms of the counterbalance-levers in such a manner as to hold the longer arms of the latter out of engagement with the contacts when the weight of the lamp is supported thereon.

698,798. STRAW-STACKER. JOHN E. BUCKWALTER, Kinston, Pa. Filed Nov. 9, 1901. Serial No. 81,714. (No model.)

Claim.—1. A straw-stacker, comprising in combination the elevator or conveyor and the idle rolls arranged at the lower end of said conveyor and between which the chaff is adapted to fall, substantially as set forth.

2. A straw-stacker, comprising in combination a conveyor or elevator, the rollers arranged at the lower end thereof, and the blower arranged beneath the rollers for the purpose described.

3. In a straw-stacker, the combination with the conveyor, of the rollers arranged at the bottom thereof, the endless belt for delivering the straw to the said rollers, a conveyor, and a rotary blower arranged beneath the rollers for the purpose described.

4. In a straw-stacker, a conveyor, comprising the upper and lower sections, the upper section telescoping upon the lower section, the sides of said upper section having guideways and rack-teeth, guide-rollers, pinions and operating mechanism carried by the lower section, as and for the purpose described.

698,794. CHAIN WRENCH. GEORGE W. BURNETT, Brooklyn, N. Y., assignor to J. H. Williams and Company, Brooklyn, N. Y., a Corporation of New York. Filed July 12, 1901. Serial No. 66,185. (No model.)

Claim.—1. A chain wrench having, in combination, a handle having a cylindrical section at one end separated from the rest of the handle by a shoulder and a screw-threaded end at the outer end of said cylindrical section; a central head composed of a single piece having opposite continuous grip-faces with projecting chain-retaining shoulders at the side edges, said grip-faces extending across the plane of the handle, said head having a cylindrical socket terminating near the apex of the head in a screw-threaded recess, said socket and recess receiving the cylindrical section and screw-threaded end of the handle; a swivel-block turning on the cylindrical section of said handle between the base of the head and the shoulder of the handle, said swivel-block having on one side a chain connection and on the other side of the handle locking provisions; and a flat chain having locking-stops, said chain being pivoted to said swivel-block on one side and being adapted to be carried over the head in cooperation with the grip-faces thereof and to be locked to said swivel-block

locking provisions on the other side of the handle, said head and chain being so related that the article operated upon is grasped squarely between the chain and one grip-face of the head, and the chain comes in contact with the other grip-face.

2. A chain wrench having, in combination, a handle; a central head having opposite continuous grip-faces extending across the plane of the handle; a swivel-block turning on said handle at the base of the head, said swivel-block having on one side a chain connection and on the other side of the handle locking provisions; and a chain pivoted to said swivel-block on one side and being adapted to be carried over the head in cooperation with the grip-faces thereof and to be locked to said swivel-block locking provisions on the other side of the handle, said head and chain being so related that the article operated upon is grasped squarely between the chain and one grip-face of the head, and the chain comes in contact with the other grip-face.

3. A chain wrench having, in combination, a handle; a central head having opposite continuous grip-faces extending across the plane of the handle; a swivel-block turning on said handle at the base of the head, said swivel-block having on one side a chain connection and on the other side of the handle locking provisions; and a chain pivoted to said swivel-block on one side and being adapted to be carried over the head and to be locked to said swivel-block locking provisions on the other side of the handle, said head and chain being so related that the article operated upon is grasped squarely between the chain and one grip-face of the head, and the chain comes in contact with the other grip-face.

4. A chain wrench having, in combination, a handle; a central head having opposite continuous grip-faces extending across the plane of the handle; and a swiveled chain adapted to be carried from one side over the head and to be locked on the other side, said head and chain being so related that the article operated upon is grasped squarely between the chain and one grip-face of the head, and the chain comes in contact with the other grip-face.

5. A chain wrench having, in combination, a handle; a central head having opposite continuous grip-faces extending across the plane of the handle and having projecting chain-retaining shoulders at the side edges; a swivel-block turning at the base of the head, said swivel-block having on one side a chain connection and on the other side of the handle locking provisions; and a chain pivoted to said swivel-block on one side and being adapted to be carried over the head between the projecting shoulders thereof and to be locked to said swivel-block locking provisions on the other side of the handle, said head and chain being so related that the article operated upon is grasped squarely between the chain and one grip-face of the head, and the chain comes in contact with the other grip-face.

698,795. CURTAIN-BRACKET. HENRY L. BURN, Boston, Chs. Filed Oct. 12, 1901. Serial No. 70,126. (No model.)

Claim.—1. A curtain-pole bracket comprising a support adapted for attachment to a window or door, arms projecting from the support

and rigidly associated therewith, a rotatable upright adjustably connected with the arm, a curtain-pole secured to the lower portion of the said upright, a plurality of uprights associated with the curtain-pole, and brace-rods rigidly connected with the series of uprights, substantially as described.

2. A curtain-pole bracket comprising a support adapted for attachment to a window or door, arms projecting from the support and rigidly associated therewith, a rotatable upright adjustably connected with the arm, a curtain-pole secured to the lower portion of the said upright, a plurality of uprights associated with the curtain-pole and progressively increasing in height from the free end of the pole toward the rotatable upright, and a pair of brace-rods rigidly connected with the whole series of uprights, the lower one of which occupies a plane parallel with the curtain-pole and the other at an angle with relation thereto.

98,796. STOVE OR RANGE. EDWIN R. CAMMERS, Newark, N. J.
Filed Feb. 4, 1897. Serial No. 681,904. (No model.)

Claim.—1. In a stove, the combination with the sides thereof provided with integral inwardly-extending flanges, and a removable air-dust having a sectional shoe-frame at its lower end, said shoe-frame supporting a perforated tip or tips, substantially as set forth.

2. In a stove, the combination with the sides of the stove, provided with integral inwardly-extending flanges which conform to the configuration of an air-dust supported by said flanges, and an air-dust made in sections said air-dust supporting in its lower portion one or a series of removable tips, substantially as described.

3. In a stove, the combination with the sides, of a fuel-magazine therebetween, integral inwardly-extending flanges projecting within the fuel-magazine and from said stove sides, a removable sectional air-dust supported thereby, and adjustable means in the lower portion of the air-dust for supporting a removable tip or tips, substantially as set forth.

4. In a stove, the combination with the sides of the stove, of a sectional air-dust therebetween open at the ends, said sides being open opposite to said ends, and supports or seats on said sides arranged around said openings which support and lock said dust, substantially as described.

5. In a stove, the combination with the sides of the stove having openings therein, of an air-dust therebetween opposite to said openings and supported or seated on said sides, and a stove-top having depending flanges lying against the upper edges of said sides of the dust, substantially as described.

6. In a stove, the combination with the sides of the stove having openings therein, of an air-dust therebetween opposite to said openings, and supported on said sides, and having shoulders at its upper edges, and a stove-top having depending flanges forming a joint with said shoulders, substantially as described.

7. In a stove, the combination with the sides of the stove, of an air-dust therebetween, said sides being each provided with two flanges, one extending around the bottom of said dust and outside the same, and the other inside the dust and below the upper portion of the same, said dust being supported at each end on said flanges, substantially as described.

8. In a stove, the combination with a pendant air-dust, the ends of the dust having air-inlets, and a damper located within said air-dust below the air-inlets, substantially as described.

9. In a stove, the combination with a pendant air-dust, extending transversely of the stove, a damper located across said air-dust, consisting of a stationary dotted motion, supported by the air-dust, and a movable dotted section located on top of the stationary section, capable of transverse movement by a handle from the outside of the stove, substantially as described.

10. In a stove, the combination of a stove-top plate having air inlets or perforations, an air-dust extending downwardly from said top plate below said air-inlets, and a drip water or liquid conduit disposed within the dust to catch water passing through said air-inlets and conduct the same to the inside of the stove, substantially as described.

11. In a stove, the combination of the air-dust open at the bottom, tip or tips removably secured in a shoe-frame locked in the side walls of

the air-dust, and located in or across the openings, substantially as described.

12. In a stove, the combination with a perforated pendant air-dust, a perforated corrugated shield located on the front side of said air-dust the ridges of the corrugated shield having ledges which overhang the perforations, and air-chambers formed between the front wall of the air-dust and the opposed corrugations of the shield, substantially as described.

13. A pendant air-dust provided with a modified shoe detachably-secured thereto for supporting one or more tips, substantially as described.

14. In a stove, the combination with the sides thereof, a pendant air-dust composed of sections, and a detachable sectional shoe with tips secured thereto, substantially as set forth.

15. In a stove, the combination of the air-dust open at the bottom and the shoe-sections inserted in or across said openings, and removably secured in said dust, said sections having projections extending within said dust, whereby said sections may be united, substantially as described.

16. In a stove, the combination of the air-dust open at the bottom, and the shoe-sections inserted in or across said openings, and removably secured in said air-dust, said sections being provided with the inwardly and upwardly apertured lugs 11, 12, for uniting the same, substantially as described.

17. In a stove, the combination of the air-dust open at the bottom, and the shoe inserted in or across said opening, said shoe having a pivotal or trunnion engagement with one side of the dust, and a positive detachable connection with the opposite side, substantially as described.

18. In a stove, the combination of the air-dust open at the bottom, and the shoe inserted in or across said opening, said dust and shoe having the sections 14 and half-trunnions 15 registering with each other at one side, and a positive detachable connection at the opposite side, substantially as described.

19. In a stove, the air-dust comprising two sections, the front section having a cut-away portion at the bottom, a longitudinal strip, and a hole above said strip, in combination with a shoe inserted in or across said cut-away portion and secured to said strip, and a shield covering said hole, substantially as described.

20. A detachable shield for a pendant air-dust, having a series of vertically-arranged perforated corrugations the ridges of said corrugated shield having ledges which overhang the perforations said shield being attached in the air-dust by a bolt projecting from the latter through a perforation in the shield, and locked thereto by suitable means, substantially as described.

21. In a stove, the combination of an air-dust, a ribbed shield therefor, and a shoe carried at the bottom of said dust, said shoe having ribs continuous with the ribs of the shield, substantially as described.

22. In a stove, the combination of an air-dust, a shoe therefor, and a tip held in said shoe, said shoe having ribs extending substantially flush with the front face of said tip, substantially as described.

23. In a stove, the combination of an air-dust, a removable shoe held thereto, and a removable tip held within said shoe, substantially as described.

24. In a stove, the combination of an air-dust, a sectional removable shoe held thereto, and a plurality of removable shoe-tips held between the sections of the shoe, substantially as described.

25. In a stove the combination of an air-dust, flanged shoe-sections held to said dust, and a shoe-tip supported by the flanges of the shoe-sections, substantially as described.

26. In a stove, the combination of an air-dust, shoe-sections held to said dust having terminal registering projections and recesses for distancing said shoe-sections, and a shoe-tip held between said sections, substantially as described.

27. In a stove, the combination of an air-dust, a shoe held to said dust having a front grooved flange, and a shoe-tip supported by said flange, and having grooves registering with the grooves of the flange, substantially as described.

28. In a stove, the combination with an air-dust, of a hollow perforated shoe-tip of fire-brick, or the like refractory material, secured on the lower edge of said dust and having a flange projecting forwardly under said dust to protect the same from the action of the heat, substantially as described.

29. In a stove, the combination with an air-dust open at the bottom, of a plurality of hollow perforated shoe-tips arranged side by side and having air-chambers formed between each other when placed within said dust substantially as described.

30. In a stove, the combination with an air-dust, of a plurality of hollow perforated shoe-tips supported on the bottom of said dust, side by side, having registering grooves on their contiguous faces, substantially as described.

31. In a stove, the combination with an air-dust of a hollow perforated shoe-tip having front and rear flanges to support the same within

the duct, and adjustable means secured to the duct for supporting said cheo-tips, substantially as described.

32. In a stove, the combination with an air-duct, of a plurality of cheo-tips arranged side by side therein, each having overhanging flanges at the sides, engaging the flanges of adjoining tips to form fixed thereunder, substantially as described.

33. In a stove, the combination of a fuel-bed, a top plate, and an air-duct extending downward from the top plate to a short distance from the fuel-bed, to form a contracted neck or fuel-passage, the contraction of said neck being proportioned to the character of fuel used, whereby different varieties of fuel can be used, substantially as described.

34. In a stove, the combination with a depending air-duct supported at the sides of the stove, means in the front of the stove for regulating the draft, a damper arranged in the side plates inside the fuel-chamber, air-passages or ducts in side plates inside the fuel-chamber, said air-passages leading from near the top of the chamber down and curved into the ends of the air-duct, substantially as described.

35. In a stove, the combination with the sides thereof, an air-duct made in two sections, two flanges for supporting said duct projecting from and formed with said sides one of said supports extending from near the top, down and then up and terminating at a point a greater distance from the top than the opposite side, the other support starting between the upper ends of the former support and extending toward the rear below the upper end of the rear portion of said former support, substantially as described.

36. In a stove, the combination with the sides thereof, supports projecting from said sides, the shape of which conforms to the configuration of an air-duct supported thereby, a sectional air-duct seated or supported therein, the upper ends of said sections being so bent as to form a reduced neck when placed together, the lower central portion of each section being cut out, and a cheo carrying a tip or tips located in the space in the bottom of the air-duct, substantially as described.

37. In a stove, the combination with the sides, of supports integral therewith for supporting a removable air-duct, means for supporting a frame in the lower portion of the air-duct, and said frame supporting one or more tips, substantially as described.

38. The combination with a fuel-magazine of a stove divided by a removable sectional air-duct, of a sectional frame in the lower portion of said air-duct, means for locking the same to said air-duct, and perforated cheo-tips locked and supported therein, said tips having grooves which register with grooves in the frame forming air-passages when said tips and frame are placed together, substantially as set forth.

39. A frame for supporting tips at the lower portion of a removable air-duct made in two sections, means for locking the parts of said frame together, and means for locking cheo tip or tips therein, substantially as described.

40. In a stove, the combination with an air-duct, composed of sections and open at the bottom, the front section being of skeleton formation, a shield secured to the front section, and means for supporting said air-duct, substantially as described.

41. In a stove, the combination with an air-duct composed of sections and open at the bottom, the front section being of skeleton formation, a shield secured to the front section, and means projecting from the stove sides for supporting and locking the duct-sections in a fixed position, substantially as described.

42. In a stove, the combination with an air-duct composed of sections and open at the bottom, the front section being of skeleton formation, a shield secured to the front section, a cheo-frame supported in said open bottom, one or a plurality of cheo-tips detachably secured to said cheo-frame, and means for supporting and locking the duct-sections in a fixed position, substantially as described.

43. In a stove, the combination with an air-duct composed of sections and open at the bottom, the front section being of skeleton formation, a shield secured to the front section, a separable cheo-frame having internal flanges at the lower end supported in said open bottom of the air-duct, one or a plurality of cheo-tips having overhanging flanges at the upper ends said flanges resting on the internal flanges at the lower end of the cheo-frame, and means for supporting and locking the air-duct sections in a fixed position, substantially as described.

44. In a stove, the combination with the fuel-magazine, a separable air-duct open at its bottom and supported in said fuel-magazine, one or a series of perforated cheo-tips supported in the open end of the air-duct, means for supplying air to said air-duct, and means on the sides of the fuel-magazine for supplying air to the sides of the fuel, said means comprising a shield having a series of interrupted downwardly-extending and rearwardly-curved ribs leading to the air-duct, substantially as described.

45. In a stove, the combination with the sides of the stove provided with inwardly-extending flanges, and a removable sectional air-duct located between said sides, the air-duct sections being locked together and

supported by the flanges projecting from the stove sides, substantially as described.

46. In a stove, the combination with the sides of the stove provided with inwardly-extending flanges, a removable sectional air-duct located between said sides, the air-duct sections being locked together and supported by the flanges projecting from the stove sides, a detachable cheo-supporting frame locked to the open end of the air-duct, and a series of detachable cheo-tips supported in said cheo-frame, substantially as described.

47. In a stove, the combination with a fuel-magazine, of a partition or air-duct therein, and a shield secured to said air-duct or partition, said shield being provided with a series of perforations vertically arranged, and ledges or overhanging flanges projecting over said perforations, substantially as described.

48. In a stove, the combination with a fuel-magazine, of a partition or air-duct therein, a vertically-ribbed shield secured to said air-duct or partition, said ribs being provided with a series of perforations, and ledges or overhanging flanges projecting over said perforations, substantially as described.

49. In a stove, an air-duct, a shield attached to said air-duct, corrugations in said shield, and corrugations having perforations and ledges or flanges overhanging said perforations.

50. In a stove, the combination with an air-duct, open at the bottom and made in two sections, means having depending spaced-apart projections secured in the open bottom for distributing air to the fuel, means for supporting said air-duct, and a corrugated shield attached to the air-duct, substantially as described.

51. In a stove, the combination with an air-duct open at the bottom, a loosely-fitting tip secured in said open bottom forming air-ducts between the duct and tip, and a perforated shield attached to said air-duct the shield being so positioned as to form an air-chamber between said shield and air-duct, substantially as described.

52. In a stove, the combination of an air-duct, a plurality of tips each comprising a reduced covering and a depending end, said depending ends adapted to form spaces or notches between each other when secured to the air-duct, substantially as described.

53. In a stove, the combination with an air-duct, and a plurality of tips each comprising a reduced covering and a depending end, said depending ends adapted to form spaces between each other when secured to the air-duct, and a series of openings communicating with the air-duct being formed in the meeting ends of the tips, substantially as described.

54. In a stove, the combination with a pendant air-duct supported by the stove sides, means for supplying air to the ends of said duct, and a plurality of removable means in the lower end of said duct whereby air-ducts are formed therebetween for distributing air to the fuel, substantially as described.

55. In a stove, the combination with an air-duct means for supporting said duct, means for supplying air to the ends of said duct, a plurality of perforated tips supported in the lower end of said duct and means in said duct for regulating the exit of air through the perforations in said tips, substantially as described.

56. In a stove, the combination with an air-duct made in sections, a perforated corrugated shield attached to the front section, forming air-passages between the duct and said shield, a removable cheo-frame in the lower end of said duct, a plurality of spaced-apart tips removably secured in said cheo-frame forming air-ducts between said tips, and means in the air-duct for regulating the admission of air, substantially as described.

57. In a stove, the combination with a fuel-magazine, an air-duct, means for introducing air to said duct, means for introducing air to the fuel-magazine, means removably secured in the lower end of the air-duct for supporting a plurality of removable spaced-apart tips and means in the air-duct for regulating the supply of air to the fuel-magazine, substantially as described.

58. In a stove, the combination with a fuel-magazine, an air-duct open at the bottom, said air-duct comprising a frame, a perforated shield removably secured to said frame, a cheo-frame hinged in the bottom of said duct, and a series of tips removably secured in said frame, substantially as described.

59. In a stove, the combination with a fuel-magazine, an air-duct, means for supporting said duct, and means hinged in the lower portion of said duct for distributing air to the fuel, substantially as described.

60. In a stove, the combination with a fuel-magazine, an air-duct, means for supporting said duct, a cheo-frame hinged in the lower portion of said duct, and a plurality of tips removably secured in the cheo-frame, substantially as described.

61. In a stove, the combination with a fuel-magazine, an air-duct open at the bottom, a sectional cheo-frame hinged in said open end and having a series of notches and projections, a plurality of tips locked in said sectional frame each tip having a series of notches, and a shield pro-

vided with ribs secured to the air-duct the ribs being in alignment with the ribs on the cheo-frame, and the notches in the tips and cheo-frame being in continuity with each other to form air-ducts, substantially as described.

62. In a stove, the combination with an air-duct made in sections, a perforated corrugated shield attached to the front section, forming air-passages between the duct and said shield, a removable cheo-frame in the lower end of said duct, a plurality of spaced-apart cheo-tips removably secured in said cheo-frame forming air-ducts between said tips, and means for regulating the admission of air, substantially as described.

63. In a stove, the combination with a fuel-magazine, an air-duct, means for introducing air to said duct, means for introducing air to the fuel-magazine, means removably secured in the lower end of the air-duct for supporting a plurality of removable spaced-apart tips and means for regulating the supply of air to the fuel-magazine, substantially as described.

64. In a stove, the combination with the sides of the stove provided with integral inwardly-extending flanges, and a sectional air-duct located between said sides, said air-duct being supported and locked together by the integral flanges projecting from the stove sides, substantially as described.

65. In a stove, the combination with the sides of the stove provided with integral inwardly-extending flanges, and a removable air-duct having a sectional cheo-frame at its lower end, and removable means secured within said frame for distributing heated air, substantially as described.

66. In a stove, the combination with the sides of the stove provided with integral inwardly-extending flanges and a removable air-duct having a removable cheo-frame at its lower end, and removable means secured within said frame for distributing heated air, substantially as described.

67. In a stove, the combination with a fuel-magazine, an air-duct open at the bottom, said air-duct comprising a frame, a perforated shield removably secured to said frame, a cheo-frame hinged in the bottom of said duct, and a series of tips having air-passages between each other and removably secured in said frame, substantially as described.

68. In a stove, the combination with a fuel-magazine, an air-duct open at the bottom, means for introducing air to said duct, means for introducing air to the fuel-magazine, means secured in the lower end of the air-duct for supporting a plurality of removable spaced-apart tips, and means for regulating the supply of air to the fuel-magazine, substantially as described.

69. In a stove, the combination with the sides of the stove provided with integral inwardly-extending flanges, a removable air-duct having a cheo-frame at its lower end, and removable means within said frame for distributing air, said means having a plurality of depending portions which form a series of spaces for the free circulation of the air, substantially as described.

70. In a stove, the combination with the sides of the stove provided with integral inwardly-extending flanges, a removable air-duct having a cheo-frame at its lower end, and a plurality of tips having spaces between each other which communicate with the air-duct for the exit of air, substantially as described.

71. In a stove, the combination with an air-duct, open at the bottom and made in two sections, means for supporting said air-duct, a plurality of devices secured in the open bottom for distributing air to the fuel, said devices being spaced apart at the upper covering ends to form air-ducts, and a shield attached to the air-duct, substantially as described.

72. The combination with an air-duct made in two sections and supports projecting from the stove sides, the supports locking and holding said sections of the air-duct together, substantially as described.

73. In a stove, the combination with a pendant air-duct open at the bottom, tips removably secured in a cheo-frame locked to the duct, substantially as described.

74. In a stove, the combination with an air-duct, a tip or tips on the lower end of said duct, each of said tips having a flange projecting forwardly under said duct to prevent the same from the action of the heat, substantially as described.

75. In a stove, the combination with a fuel-magazine, an air-duct, means for introducing air to said duct, means for introducing air to the fuel-magazine, means removably secured to the lower end of the air-duct for supporting a plurality of removable spaced-apart tips, and means for regulating the exit of air from the duct to the fuel-magazine, substantially as described.

76. In a stove, the combination with the sides of the stove, flanges projecting inwardly from said sides and a removable air-duct having a sectional cheo-frame at its lower end, and removable means secured within said frame for distributing heated air, substantially as described.

77. In a stove, the combination with a fuel-magazine, an air-duct supported therein, said air-duct being made in sections, supports projecting from the sides of the stove, said supports locking and holding the sections together, and a plurality of tips supported at the lower end of the sectional air-duct.

78. In a stove, the combination with an air-duct made in two sections, and supports projecting from the stove sides, the supports locking and holding said sections of the air-duct.

698,797. HEATING-STOVE. EDWIN R. GARDNER, Newark, N. J.
Filed May 12, 1900. Serial No. 716,886. (No model.)

Claim.—1. A stove comprising a casing, a fire-pot, said fire-pot having a series of openings in the lower portion which communicate with a space or chamber formed between the casing and the fire-pot, through which the products of combustion pass, an exit-flue communicating with said space or chamber pipes or tubes depending within and arranged around the fire-pot for delivering currents of air through the fuel to the exit-flue, and castings or tubes for introducing individual currents of air around the under side of the fuel, substantially as described.

2. A stove comprising a casing, a fire-pot, a pipe or tube loosely suspended and directed toward said fire-pot, and means for loosely supporting said pipe or tube comprising a bar in the tube-support, a bar in the top of the tube, and a connecting-link between said bars substantially as described.

3. In a heating-stove, the combination with the fire-pot, air-duct openings to supply air at various angles downwardly above the fuel-bed, a hot-air chamber surrounding said fire-pot, a damper operating over said openings, an exit-flue communicating with the air-chamber at the upper end thereof, an air-heating chamber, a series of loosely-hung pipes or tubes depending from said latter air-heating chamber toward the fuel-chamber adapted to deliver heated air downwardly through the fuel under the influence of the draft, and castings or tubes for introducing individual currents of heated air in the hot-air chamber and around below the fuel, substantially as described.

4. In a heating-stove, the combination with the fire-pot surrounded by an air-chamber, an exit-flue communicating with the air-chamber at the upper end, openings in said fire-pot which communicate with said air-chamber for delivering heated air to the body of fuel from the under side, castings or tubes for introducing hot air to the air-chamber, downwardly and at an angle, and depending pipes or tubes for delivering air downwardly through the bed of fuel, the air delivered through the pipes meeting the hot air coming from the castings or tubes under the fuel which mixes with and increases the convection gases under the influence of the draft of the stove, as set forth.

5. In a heating-stove, the combination with the fire-pot, a chamber surrounding said fire-pot, an exit-flue communicating with said chamber, the lower portion of said fire-pot having a series of openings, means for directing hot air through said openings to and through the body of fuel, a hot-air chamber, and a series of depending tubes communicating with said chamber, said tubes delivering heated air above and through the fuel to meet and mix with the air delivered through the openings in the lower portion of the fire-pot, said mixed air-currents being drawn through the openings in the lower portion of the fire-pot to the exit-flue, substantially as described.

6. In a heating-stove, the combination with the fire-pot made in sections, the upper section being tapered toward the top on its inner side and opened at both ends, and the lower section being provided with openings, an air-chamber formed between said fire-pot and the casing, means for supplying air to said air-chamber, an air-duct flue communicating with said chamber, and a series of pipes for delivering currents of air downwardly through the fuel from the top, under the influence of the main draft, substantially as described.

7. In a heating-stove, the combination with a fire-pot composed of an upper section having a series of tapering grooves, the latter being deepest at the top, and a lower section having a series of openings, an

air-heating chamber surrounding said fire-pot and provided with an exit-flue, a plurality of depending tubes adapted to deliver currents of heated air above and through the bed of the fuel, and a damper for regulating the admission of air to the fire-pot, substantially as described.

8. A heating-stove comprising a fire-pot made of a lower section provided with a series of openings, and an upper section having its inner wall tapering and provided with a series of corrugations, an air-heating chamber surrounding said fire-pot, an exit-flue communicating with said air-heating chamber, and means for delivering a plurality of air-currents through the fuel from the top, substantially as described.

9. A heating-stove comprising a fire-pot made up of a lower section having a series of openings, and an upper section having its inner wall tapering and provided with a series of horizontal corrugations, in combination with an air-heating chamber surrounding said fire-pot, an exit-flue communicating with said air-heating chamber, and means for delivering a plurality of air-currents through the fuel from the top, substantially as described.

10. In a stove, the combination with a fire-pot composed of an upper section which is of tapering formation internally, the widest portion being at the bottom, and a lower section having a series of openings, an air-heating chamber surrounding the fire-pot and communicating with said pot through the openings in the lower section, means for delivering air above the bed of the fuel, means for delivering air to the air-heating chamber, said latter volume of air meeting the volume of air delivered above the fuel as the same is diffused by the conical formation of the upper section of the fire-pot, substantially as described.

11. A stove comprising a casing, a fire-pot, and means for delivering heated air to said fire-pot, said means consisting of a frame open at the front and provided with a window, an opening in the under side of said frame, and a groove in the casing leading to said opening to direct air thereto, substantially as described.

12. A stove comprising a casing, a fire-pot, and means for delivering heated air to said fire-pot, said means consisting of a frame having an opening in its under side, and a groove in the casing leading to said opening to direct air thereto, substantially as described.

13. In a stove, the combination with the casing, a grate, a fire-pot composed of a lower section made up of a series of radially-disposed and spaced-apart partitions, and an upper section seated on said lower section, means for supplying air through the spaces between the partitions, and means for delivering air above and in the fire-pot, substantially as described.

14. In a stove, the combination with the casing, a grate, a fire-pot composed of a lower section made up of a series of radially-disposed and spaced-apart partitions, and an upper section supported by said lower section, the internal wall of said upper section having a series of vertical grooves the latter being larger at the upper end of said section, means for supplying air through the spaces between the partitions, and means for delivering air above and in the fire-pot, substantially as described.

15. In a stove, the combination with the casing, a grate, a series of vertically-spaced partitions above the grate, said partitions extending out therefrom into an air-chamber forming air channels or passages, and a fire-pot section mounted on the upper end of said partitions, the interior wall of said section being tapered and provided with a series of grooves, said grooves increasing in size from the bottom to the top of said section, substantially as described.

16. In a stove, the combination with the stove structure, a grate, a fire-pot composed of a lower section made up of a series of vertically-spaced partitions above the grate, an upper section mounted on said partitions the inner wall of which is conical and provided with a series of vertical grooves, an air-chamber surrounding said fire-pot, hollow trunks or passages communicating with the air-chamber, the outer side of each housing or trunk having a perforation for introducing heated air to the air-chamber, from whence it passes through the spaces between the vertical partitions to the body of fuel, an air-chamber located in the stove structure and above the fuel-magazine, a series of pipes or tubes depending from said air-chamber to and within the fire-pot, a series of trunks or tubes in the stove sides communicating with the fire-pot, and dampers for controlling the admission of air to the depending tubes, and the trunks or tubes in the side of the stove, substantially as described.

17. In a stove the combination with the casing, a grate, a fire-pot composed of two sections, the lower section being made of a series of spaced-apart partitions above the grate, and the upper section mounted on said partitions, and an air-chamber with means for introducing air thereto, the partitions forming the lower portion of the fire-pot projecting into the air-chamber forming the passages or channels for the air to be delivered to the fuel, substantially as described.

18. A stove comprising a casing, a grate, a fire-pot composed of two sections, the lower section being made up of a series of vertical partitions above said grate, each formed in the upper ends of the vertical partitions,

the upper section having its interior smaller at the top than at the bottom, said section being mounted in and supported by the caps in the upper ends of the vertical partitions, an air-heating chamber, the partitions extending out and within said chamber, and means for supplying said chamber with air, substantially as described.

19. In a stove, the combination with a fire-pot having a series of openings at its lower portion, a chamber surrounding said fire-pot, means for introducing air to said chamber, a series of tubes arranged to deliver individual currents of air to the top of the fuel at an angle, a flue, an air-heating chamber, a tube communicating with said air-heating chamber to direct currents of heated air downwardly to the top of the fuel, substantially as described.

20. In a heating-stove, the combination with an air-chamber, a fire-pot, air-opening in the lower portion of said fire-pot, a frame or flange mounted within said casing which communicates with said air-chamber, the fire-pot being in communication therewith through the opening in its lower portion, the frame having openings located in the under side thereof, and an inclined baffle channel or surface on the stove-casing located under said openings, substantially as described.

21. In a heating-stove, the combination with a stove-casing, a fire-pot having openings in the lower portion thereof, a corrugated section formed in the upper part thereof, a series of dampened tubes or trunks arranged in the casing and above the fire-pot, and a series of openings being arranged in the lower part of the casing to deliver heated air to said fire-pot to communicate with the air delivered thereto through the tubes, substantially as described.

22. In a heating-stove, the combination with a casing, a fire-pot, which tapers internally toward the top and is provided with openings at the bottom, an air-chamber surrounding said fire-pot, means for introducing air thereto, an air-chamber, tubes communicating with said chamber for delivering air downwardly into the fire-pot, and a series of trunks or tubes located in the casing and adapted to introduce air to the fire-pot independently of the tubes communicating with the air-chamber, substantially as described.

23. In a heating-stove, the combination with a casing, a fire-pot which tapers toward the top and is provided internally with vertically-arranged grooves, a space being formed between said fire-pot and the casing, an exit-flue communicating with said space, and means for introducing currents of heated air through the fuel from the top under the influence of the draft, substantially as described.

24. In a downward-stove, the combination of a support for fuel, a series of air-supply tubes arranged contiguous with the front and side walls of the same to direct jets of air downwardly through the fuel, and a series of air-tubes arranged intermediate of the tubes at the side walls for delivering air downwardly through the fuel, substantially as described.

25. In a downward-stove, the combination of a support for fuel, an exit-flue, a series of supply-tubes arranged contiguous with the front and side walls of the same to direct jets of air downwardly through the fuel, a series of air-tubes arranged intermediate of the tubes at the side walls for delivering air downwardly through the fuel, and a plurality of passages located near the bottom of the stove, and communicating with the exit-flue, substantially as described.

26. In a stove, the combination with a fire-pot, a flue, which communicates with the fire-pot at the lower end, an air-heating chamber which is supplied with air direct from the atmosphere, and a series of tubes communicating with said air-heating chamber for directing currents of heated air downwardly through the fuel from the top which mixes and ignites the gases coming under the influence of the main draft, substantially as described.

27. In a stove, the combination with a fire-pot, a flue, an air-heating chamber, a series of tubes communicating with said air-heating chamber for directing individual currents of heated air downwardly through the fuel from the top, a separate series of tubes arranged at an angle to direct individual air-currents to the top of the fuel under the influence of the main draft, and means for controlling the admission of air to said tubes, substantially as described.

28. In a stove, the combination with a fire-pot, an air-heating chamber, a series of tubes communicating with said air-heating chamber for directing currents of heated air downwardly through the fuel from the top under the influence of the main draft, an air-heating chamber surrounding said fire-pot, a flue communicating with said air-heating chamber at the lower end, and castings or tubes for introducing individual currents of air at various angles to the lower portion of the fire-pot to mix with the heated air delivered thereto by the aforesaid tubes, substantially as described.

29. In a stove, the combination with a fire-pot, an air-heating chamber, a series of tubes communicating with said air-heating chamber for directing currents of heated air downwardly through the fuel from the top under the influence of the main draft, an air-heating chamber surrounding said fire-pot, a flue communicating with said air-heating chamber

ber, and castings or tubes for introducing individual currents of heated air at various angles to the air-heating chamber and thence to the lower portion of the fire-pot to mix with the heated air delivered thereto by the aforesaid tubes, substantially as described.

30. In a stove, the combination with a fire-pot, having openings in its lower portion, an air-heating chamber, tubes communicating with said air-heating chamber for directing currents of heated air downwardly through the fuel from the top, an air-heating chamber surrounding said fire-pot and communicating with the latter, a plurality of means for introducing heated air to said chamber, and means for delivering heated air to said plurality of air-introducing means, substantially as described.

31. In a stove, the combination with a fire-pot, which is open at the bottom and of tapering formation internally, the narrowest portion being at the top, said internally-tapering portion having a series of grooves, an air-heating chamber surrounding said fire-pot, means for introducing heated air to said chamber, an exit-flue communicating with said chamber, and a plurality of tubes for directing air-currents downwardly through the fuel from the top under the influence of the draft, substantially as described.

698,798. STOVE. ROBERT E. GARDNER, Inventor, E. J. Fild May 13, 1899. Serial No. 717,446. (No model.)

Claim.—1. In a stove, the combination with a pendant air-dust open at the bottom, shields secured to the front and rear of said air-dust, and removable means within the bottom of said dust for distributing heated air, substantially as described.

2. In a stove, the combination with a pendant air-dust, shields secured to said dust, removable heat-distributors secured within the lower end of said dust, a fuel-magazine, air-heating pipes, said pipes communicating with the air-dust and the atmosphere, and means for regulating the admission of air to said pipes, substantially as shown and described.

3. In a stove, the combination with a fuel-magazine, a pendant air-dust, right-angled air-heating pipes within the fuel-magazine, the horizontal portion of said pipes entering the air-dust at the upper end of the latter and the vertical portion of said pipes communicating with the atmosphere, and means for regulating the admission of air to said pipes, substantially as shown and described.

4. In a stove, the combination with a pendant air-dust, open at the lower end, of detachable shields on the front and rear of said air-dust, removable flaps secured within the lower end of said dust, and air-inlet pipes entering the air-dust through the shields, substantially as shown and described.

5. In a stove, the combination with a fuel-magazine a pendant air-dust located within said fuel-magazine, shields on each side of said air-dust, and air-heating distributor or distributors removably secured within the lower open end of the air-dust, substantially as shown and for the purpose set forth.

6. In a stove, the combination with a fuel-magazine, a pendant air-dust located within said fuel-magazine, air-inlet pipes entering each end of said air-dust, said air-inlet pipes being located across the upper part and extending downwardly within the fuel-magazine, to a point above the grate, and means for regulating the admission of air to said pipes, substantially as shown and for the purpose set forth.

7. In a stove, the combination with a fuel-magazine, an air-dust, pipes located in said fuel-magazine, said pipes communicating with the atmosphere for supplying air to said air-dust, a flue out in from the sides of the stove to form an air-heating chamber, said flue having air-exits communicating with the fuel-magazine, and means for regulating the supply of air to said chamber, substantially as shown and described.

8. In a stove, the combination with a fuel-magazine, a pendant air-dust, means for supplying said air-dust with air at both ends, a perforated lining in said fuel-magazine cut in from the stove sides to form an air-heating chamber, and means for regulating the admission of air entering at

the ends of the air-dust, and the air-heating chamber, substantially as shown and described.

9. A pendant air-dust, and an air-distributor consisting of a main body portion, and a reduced portion, the latter portion fitting in said air-dust, and air-spaces being formed between said dust, and the reduced portion of the air-distributor for the escape of the air from the dust, substantially as described.

10. A pendant air-dust, and an air-distributor consisting of a main body portion, and a reduced upper portion, the latter portion fitting in said air-dust air-spaces being formed between said dust, and the reduced portion of the air-distributor, substantially as described.

11. A pendant air-dust, and an air-distributor consisting of a main body portion having a series of horizontal grooves and a reduced upper portion having a series of vertical grooves which form a continuation of the horizontal grooves in the main body portion, said upper portion fitting within said air-dust, substantially as shown and for the purpose set forth.

12. A pendant air-dust, and an air-distributor consisting of a main body portion, provided with a series of horizontal and vertical grooves, a reduced upper portion which fits within said air-dust, said portion having a series of vertical grooves which form a continuation of the horizontal grooves formed in the main body portion, and a tapering bottom, said tapering bottom forming one part of an arch, which latter is formed when two or more distributors are placed side by side, substantially as shown and described.

13. A shield for a pendant air-dust, consisting of a perforated corrugated main body portion, said corrugations gradually tapering to a straight edge and an internal flange at the bottom, the inner edge of said flange being horizontally corrugated, substantially as shown and for the purpose set forth.

14. In a stove or range, the combination with a pendant air-dust, an air-deflector and baffle-plates arranged within said air-dust, and means for directing a current of air to the air-dust, substantially as shown and for the purpose set forth.

15. The combination with a pendant air-dust, and means for breaking air in said dust, said means comprising a series of spaced-apart perforated plates, and a hood or cover supported a slight distance above the upper ends of said plates, said hood overhanging the outermost plate, substantially as described.

16. In a stove, the combination with a fuel-magazine, a perforated pendant air-dust, means secured within the lower end of said air-dust for distributing the air, and a fuel-heating plate entering said magazine, said plate being provided with air-inlet pipes, substantially as shown and described.

17. In a stove, the combination with an air-dust, a fuel-magazine, a housing having an inner and outer bottom, the former having a perforation near its outer end, said housing being formed at one side and at a point behind the air-dust, a frame carrying a sheet of wire in the outer end of said housing, and a flue communicating with the sheet, and supplying air around the inner face of the wire, substantially as shown and described.

18. In a stove, the combination with a fuel-magazine, a pendant air-dust located within said fuel-magazine, air-inlet pipes or pipes located within said fuel-magazine, the upper ends of said pipes communicating with the upper end of the air-dust and the lower ends of said pipes communicating with the atmosphere at a point near the grate, means for regulating the supply of air to the air-dust, and a plurality of air-distributors having exits formed at their meeting ends in the air-dust for distributing air, substantially as described.

19. In a stove, the combination with a fuel-magazine, a perforated air-dust having removable air-distributors secured within the lower end of said air-dust, pipes located in said fuel-magazine, said pipes communicating with the atmosphere at a point above the grate for supplying heated air to said dust, air-heating chambers located adjacent the magazine, said chambers having exits which communicate with the fuel-magazine, and means for regulating the supply of air thereto, substantially as described.

20. In a stove, the combination with an air-dust, and a plurality of air-distributors comprising covering ends and depending ends, said depending ends adapted to form arches between each other when secured to the air-dust, substantially as described.

21. In a stove, the combination with an air-dust, and a plurality of air-distributors, comprising covering ends and depending ends, said depending ends adapted to form arches between each other when secured to the air-dust, and a series of openings being arranged at right angles to each other in the meeting faces of said air-distributors, substantially as described.

22. In a stove, the combination with a fuel-magazine, a pendant air-dust, said dust comprising depending perforated plates, perforated shields provided with a series of ribs and attached to said plates, air-distributors removably secured between the lower ends of the plates, and ribs on said

distributors which form continuations of the ribs on said shield, substantially as described.

26. In a stove, the combination with a fuel-magazine, a pendant air-dust, and air-dust comprising depending plates, corrugated shields attached to said plates perforations being formed in said corrugations, an air-distributor removably connected between the lower ends of said plates and being provided with air-exits and ribs, said ribs being in alignment with and forming a continuation of the corrugations, substantially as described.

27. A shield for a pendant air-dust, corrugated in cross-section and having at its lower end a right-angled internal flange, and means co-operating with said internal end to form air-distribution, substantially as described.

28. In a stove, the combination with a pendant air-dust, means secured in the lower end of said dust for distributing heated air, and a corrugated shield having an internal corrugated right-angled flange at its lower end, said corrugations forming air-exits with the means for distributing heated air, substantially as described.

29. In a stove, the combination with a fuel-magazine, an air-dust having a plurality of apertures or notches at its lower end, means for supplying air between said apertures, air-heating chambers having air-exits adjacent the fuel-magazine, means for supplying air to said chambers, a fuel-heating duct, and air-heating pipes entering the magazine through the fuel-heating duct, substantially as described.

30. In a stove, the combination with a fuel-dust, means in said dust for admitting air, a fire-pot, a front grate, and a front door, a space being formed at the top of the grate forming communication between the fire-pot and the space between the front door and the grate, substantially as described.

31. In a stove, the combination with a fuel-dust, means in said dust for admitting air, a fire-pot, a pendant air-dust, a front grate, and a front door, a space being formed at the top of the grate forming communication between the fire-pot and the space between the front door and the grate, substantially as described.

32. In a stove, the combination with a fuel-magazine, a pendant perforated air-dust, air-heating chambers having air-exits on the side of the fuel-magazine, a removable fuel-heating duct entering said magazine, and means in said duct for introducing air to the fuel-magazine, substantially as described.

33. In a stove, the combination with a pendant air-dust, open at the bottom, a plurality of removable air-distributors secured in said open bottom, and having air-exits at their meeting edges, baffle-plates in said dust, and means for introducing air to the dust.

34. In a stove, the combination with a fuel-magazine, a pendant air-dust open at the bottom, distributors provided with air-exits secured in said open bottom, shields secured to the dust, baffle-plates in said dust, and a pipe or pipes passing through said fuel-magazine to supply air to said air-dust, substantially as described.

35. In a stove, the combination with a fuel-magazine and fire-pot, a pendant air-dust, a vertical grate, open at the top, a door covering said grate, and a fuel-chute having air-inlet pipes entering the fuel-magazine above the upper end of the grate, substantially as described.

36. In a stove, the combination with a fuel-magazine, an air-dust, air-distributors in the lower end of said air-dust, means for supplying air to both ends of the air-dust, air-heating chambers having air-tubes for introducing heated air to said fuel-magazine, means for regulating the supply of air thereto, a fuel-supply chute having air-inlet pipes entering the fuel-magazine, and means for introducing heated air to the fuel-magazine behind the air-dust, substantially as described.

37. In a stove, the combination with an air-dust, a fuel-magazine, and means for introducing heated air to the fuel-magazine, said means comprising a housing having a false bottom provided with an opening which communicates with the interior of said housing, and a flue communicating with the space between the housing and the false bottom for the admission of air, substantially as described.

38. In a stove, the combination with a fuel-magazine, an air-dust comprising depending plates and air-distributors between the lower ends of said plates, means for delivering air to the fuel in the fuel-magazine from the air-dust, and a pipe or pipes passing through the magazine for supplying air to said air-dust from the atmosphere, said pipe or pipes each having a flaring end where it enters the air-dust, and means for regulating the admission of air thereto, substantially as described.

39. In a stove, the combination with a fuel-magazine, an air-dust comprising depending perforated plates, air-distributors, a perforated shield secured to said depending plates, baffle-plates between said depending plates and shield, baffle-plates between the depending plates, and a pipe or pipes passing through the magazine for supplying air to said air-dust, substantially as described.

40. In a stove, the combination with a fuel-magazine, means for introducing air thereto, said means comprising a flue located to heat air in its passage therethrough, a protrusion or flange in proximity to said

flue, said housing having an opening which communicates with said flue, a sheet of transparent material in the housing and adjacent the opening therein, all for the purpose of supplying air to the fuel-magazine and preventing soot accumulating on the transparent material, substantially as described.

41. A pendant air-dust, open at the bottom, means for supplying air to said air-dust, and an air-distributor consisting of a pendant end, and a securing end, angular grooves in the distributor at a point where said distributor enters the air-dust, substantially as described.

42. An air-dust open at the bottom, a plurality of spaced-apart removable air-distributors having air-exits at their meeting edges and secured within the air-dust, and a sectional shield secured to said air-dust, substantially as described.

43. A pendant air-dust, and a series of air-distributors each consisting of a body portion which tapers at its lower end and is provided with horizontal and vertical grooves, a securing upper end portion which fits within said air-dust, said portions having a series of vertical grooves which form a continuation of the grooves in the body portion, said tapering ends forming spaces between said distributors when two or more of the same are placed in the air-dust, substantially as described.

44. In a stove, the combination with a fuel-magazine, a pendant air-dust, pipes in said magazine which communicate with the atmosphere and the air-dust to supply heated air to said air-dust, a perforated lining in said fuel-magazine set in from the stove sides to form an air-heating chamber, and means for regulating the admission of air entering the air-dust and the air-heating chamber, substantially as described.

45. In a stove, the combination with a fuel-magazine, a pendant air-dust, means for supplying said air-dust with heated air, a perforated lining in said fuel-magazine set in from the stove sides to form an air-heating chamber, and means for regulating the admission of air entering at the ends of the air-dust and the air-heating chamber, substantially as described.

46. A pendant air-dust, and a plurality of solid air-distributors having notches at their meeting edges to form air-exits, said distributors consisting of a main portion, and a reduced upper portion, the latter portion fitting in said air-dust, substantially as described.

47. In a stove, the combination with a pendant air-dust, an air-distributor and baffle-plates arranged within said air-dust, and means for directing currents of heated air to the air-dust, substantially as described.

48. In a stove, the combination with a fuel-magazine, a pendant air-dust open at the bottom, air-distributors provided with air-exits at their outer edges and secured in said open bottom, shields secured to the air-dust, baffle-plates in said air-dust, and means in the magazine for supplying heated air to the air-dust, substantially as described.

698,799. STOVE. EDWIN E. GARDNER, NEWARK, N. J. Filed Dec. 14, 1899. Serial No. 742,112. (No model.)

Claim.—1. In a stove, the combination with a fuel-magazine, a pendant partition therein, an air-dust, air-heating chambers in the stove structure, and superheaters located in said fuel-magazine in front of the pendant partition, said superheaters communicating with said air-heating chambers, the superheaters having outlets for delivering heated air through the body of the fuel in the magazine under the influence of the main draft.

2. In a downward-stove, the combination of a fuel-magazine, a pendant partition therein, an air-dust, means located in said fuel-magazine in front of the pendant partition for heating air, means for supplying air to

said means for heating air, and tubes extending downwardly from the means for heating air from a plane above the level of the bed of fuel and adapted to direct currents of heated air toward the bed of fuel for its combustion, all constructed for the purpose of conducting the heated air and the products of combustion downwardly through the fuel under the influence of the draft.

3. In a downward-stove, the combination of a fuel-magazine, a pendant partition therein, an air-dust, means located in said fuel-magazine in front of the pendant partition for heating air, and tapered tubes extending from the means for heating air from a plane above the level of the bed of fuel, and adapted to deliver heated air currents toward the bed of fuel for its combustion, all constructed for the purpose of conducting currents of heated air, and the products of combustion downwardly through the fuel under the influence of the draft.

4. In a stove, the combination with a fuel-magazine, a pendant air-dust, an air-dust, air-heating chambers formed in the stove structure means for regulating the supply of air to said chambers, superheaters located in said fuel-magazine in front of the pendant air-dust, said superheaters communicating with said air-heating chambers, and tapered tubes depending from said superheaters, for delivering heated air to and through the fuel-magazine, under the influence of the main draft.

5. In a stove, the combination with a fuel-magazine, air-heating chambers located in the stove structure, superheaters located in said fuel-magazine, said superheaters communicating with said air-heating chambers, and a series of tapered tubes depending from said superheaters, the ends of said tubes which are located near the center being larger than the tubes near the side walls of said stove, to uniformly supply heated air to the fuel-magazine.

6. In a stove, the combination with a fuel-magazine, air-heating chambers located in the stove structure, superheaters located in said fuel-magazine, said superheaters communicating with said air-heating chambers, and a series of tapered tubes depending from said superheaters, the ends of said tubes which are located near the center, being larger than the tubes near the side walls of said stove, to uniformly supply heated air to the fuel-magazine.

7. In a stove, the combination with a fuel-magazine, a pendant air-dust therein, an air-dust, an air-heating chamber located in the stove structure, a superheater located in front of the pendant air-dust and in said fuel-magazine which communicates with the air-heating chamber, and means connected to said superheater for delivering a uniform supply of heated air to and through the fuel-magazine under the influence of the main draft.

8. In a stove, the combination with a fuel-magazine, an air-heating chamber, adapted to receive air at both ends, and tapered tubes depending from said chamber into said magazine, the ends of said tubes which are nearest the center of the stove being greater in diameter than the end tubes, substantially as shown and described.

9. In a stove, the combination with a fuel-magazine, of a blinged fuel-door covering the fuel-opening of said magazine, air-heating chambers formed between the walls of the fuel-magazine and the stove sides, a superheater attached to said fuel-door, said superheater adapted to register with said air-heating chambers when the fuel-door is closed, and means on the superheater for uniformly introducing currents of heated air to the fuel.

10. In a stove, the combination with a fuel-magazine, a fuel-door, an air-dust in said magazine, said air-dust being provided with air-exits for delivering currents of heated air to the fuel, a superheater suspended from the top of the stove and into the magazine, a series of tubes depending from said superheater, a closed superheater attached to said fuel-door, tubes projecting from said superheater, means communicating with the superheaters for supplying heated air, and means for simultaneously and uniformly regulating the supply of air to the chambers which supply heated air to the air-dust and the superheaters.

11. In a stove, the combination with a fuel-magazine, an air-dust in said magazine, a superheater, and a series of tubes arranged side by side and depending from said superheater, the end-openings of said tubes nearest the supply opening or openings of the superheater, being smaller than the ends of the tubes furthest from said supply, to equalize and uniformly supply currents of heated air to and through the fuel-magazine.

12. In a downward-stove, the combination with a fuel-magazine, an air-heating chamber, and a plurality of tapering tubes depending from said air-heating chamber, said tubes being arranged to deliver currents of heated air toward the fuel, the end-openings of said tubes varying in size, these nearest the supply to the air-heating chamber being the smallest, all constructed for the purpose of conducting uniform currents of heated air downwardly through the fuel under the influence of the draft.

13. In a stove, the combination with a fuel-magazine, an air-dust supported therein, said air-dust being made in sections, means projecting from the sides of the stove for supporting said sectional dust, and a plu-

rality of spaced-apart tips supported at the lower end of the sectional air-dust.

14. In a stove, the combination with a fuel-magazine, an air-dust supported therein, said air-dust being made in two sections, supports projecting from the sides of the stove, said supports locking and holding the sections together, and a plurality of sectional tips supported at the lower end of the sectional air-dust.

15. In a stove, the combination with a fuel-magazine, an air-dust supported therein, said air-dust being made in sections, means for supporting said sections, and a plurality of spaced-apart sectional tips supported at the lower end of the sectional air-dust.

16. In a stove, the combination with a fuel-magazine, an air-dust supported therein, said air-dust being made in sections, means for supporting said sections, and a series of spaced-apart and hollow perforated sectional tips supported at the lower end of the sectional dust.

17. In a stove, the combination with a fuel-magazine, a sectional removable air-dust, and a sectional removable tip or tips located in the lower end of said sectional dust.

18. In a stove, the combination with sides thereof, said sides having a cut-out portion and a series of air-inlets above said cut-out portion, a fuel-magazine having a series of perforations adjacent the cut-away portions in the stove sides, and perforated panels placed on the sides of the stove covering the cut-away portions and the air-inlets, said panels having perforations on the inner sides for forming air-heating chambers for applying the perforations in the fuel-magazine and the air-inlets in the stove sides.

19. In a stove, the combination with a fuel-magazine having a series of openings in its walls, means for delivering air to various points in the fuel-magazine, a panel fitting over the perforations in the fuel-magazine having its upper portion perforated and having a cavity on its inner side and a partition for dividing said cavity into two chambers so that air is furnished independently through the perforations in the fuel-magazine and through the said means for delivering air to various points therein.

20. In a stove, the combination with a fuel-magazine, an air-dust therein, means for jolting heated air to the front of the fuel-chamber, means for delivering currents of heated air to the fuel in rear of said air-dust, said means consisting of a plurality of two provided with notched flanges, one of said flanges overlapping the flange on the next succeeding bar, air-heating chambers arranged in the front and rear of said flanges and means for directing heated air to said chambers to communicate with the air in the fuel-chambers delivered from the air-dust and the jolting means.

21. A sectional air-dust for a stove made in two sections, flanges projecting from the sides of said stove, said sections being locked together and sealed in end by said flanges, legs at the lower end of the sections, and a baffle-plate located between the upper ends of the sections.

22. In a stove, the combination with a fuel-magazine, an air-heating chamber, a superheater having depending tubes and a rearwardly-extending flange, means for supporting said superheater at its ends, an air-dust having a forwardly-projecting flange, said flange being supported on the rearwardly-extending flange of the superheater and means for supporting said air-dust.

23. In a stove, the combination with an air-superheater provided with a rearwardly-extending flange, an air-dust having a forwardly-projecting flange, said flange being supported on the rearwardly-extending flange of the superheater, and integral supports projecting from the stove sides for supporting said air-dust.

24. In a stove, the combination with an air-superheater provided with a rearwardly-extending flange, an air-dust made in two sections, one of said sections having a forwardly-projecting flange, said flange being supported on the rearwardly-extending flange of the superheater, and supports projecting from the stove sides for supporting said air-dust.

25. The combination with an air-dust for a stove, a burner plate or shield, and supports projecting from the stove sides, the air-dust and the shield being held in fixed relation to each other by being seated in said supports.

26. The combination with an air-dust having a perforated body portion, a burner plate or shield, a grate or perforated plate inserted between said perforated body portion and said burner plate or shield, said means at the lower meeting ends of the dust and shield for distributing heated air.

27. In a stove, the combination with a fuel-magazine, a series of heated-air-introducing tubes, a corresponding series of heated-air-introducing tubes arranged at an angle and approximately between the above-said series of tubes, a series of air-introducing tubes below the line of the bed of the fuel, and means for regulating the supply of air introduced through said tubes.

28. In a stove, the combination with a sectional air-dust made in two sections, means for locking said sections together, and sectional tips

supported in the lower open end of said air-dust, said tip-section being slightly spaced apart for the exit of air.

29. In a stove, the combination with a perforated air-dust, perforated shield on said air-dust, means for supporting the air-dust and shield, a series of bell-shaped tubes in the air-dust, a gasket interposed in the space formed between the air-dust and one of the shields, and a plurality of sectional tips supported in the lower end of the air-dust, said tips having air-exits.

30. In a stove, the combination with a perforated air-dust made in two sections, supports projecting from the stove sides, said supports locking and holding said sections of the air-dust, and shields secured to the front and rear of said dust.

31. In a stove, the combination with a fuel-magazine, an air-dust, tip or tips being secured to said dust, each of said tips being made in sections, means for opening said sections, and means for locking said sections together.

32. A hollow tip made in sections, said sections having notches in their edges, legs projecting from one section and adapted to enter a cut in the opposite section to form spaces between said sections, and means for locking said sections together.

33. In a stove, the combination with a fuel-magazine, a fuel-door, an air-heating chamber covered to said fuel-door, means for supplying air to said chamber, and tubes depending from the chamber into said magazine, the exits of said tubes which are nearest the means for supplying air to the air-heating chamber being of smaller area than those remote from said supply.

34. In a stove, the combination with a fuel-magazine, of a bi-ported fuel-door covering the fuel-opening of said magazine, an air-heating chamber, a superheater attached to said fuel-door, said superheater adapted to register with said air-heating chamber when the fuel-door is closed, and means on the superheater for uniformly introducing currents of heated air to the fuel.

35. In a stove, the combination with a fuel-magazine, a pendant perforated air-dust therein, an air-heating chamber, a superheater in said fuel-magazine, said superheater communicating with said air-heating chamber, and means attached to the superheater for delivering currents of heated air to and through the fuel in the magazine under the influence of the main draft.

36. In a stove, the combination with a fuel-magazine, a pendant perforated air-dust therein, an air-heating chamber, a superheater in said fuel-magazine, said superheater communicating with said air-heating chamber, and means attached to the superheater for delivering uniform currents of heated air to and through the fuel in the magazine under the influence of the main draft.

37. In a stove, the combination with a fuel-magazine, a pendant perforated partition, an air-heating chamber, a superheater in said fuel-magazine, said superheater communicating with said air-heating chamber, and a series of tubes depending from the superheater, the openings of the tubes nearest the supply of the superheater being smaller than the exits of the tubes remote from said supply, all for the purpose of delivering uniformly-heated air to and through the fuel under the influence of the main draft.

38. In a stove, the combination with a fuel-magazine, a pendant partition in said magazine, a superheater depending from the top of the stove and into the magazine, a series of tubes depending from said superheater, a second superheater attached to the stove at an angle to the above-said superheater, tubes projecting from said angularly-disposed superheater, means communicating with the superheater for supplying heated air, and means for regulating the admission of air to the superheater.

39. In a stove, the combination with a fuel-magazine, a pendant partition in said magazine, a superheater depending from the top of the stove and into the magazine, a series of tapered tubes depending from said superheater, a second superheater attached to the stove at an angle to the above-said superheater, tapered tubes projecting from said angularly-disposed superheater, means communicating with the superheater for supplying heated air, and means for regulating the admission of air to the superheater.

40. In a stove, the combination with a fuel-magazine, an air-dust supported therein, means for supporting said dust, and a plurality of speed-apart sectional tips in the lower end of said dust.

41. In a stove, the combination with a fuel-magazine, an air-dust supported therein, means for supporting said dust, and a plurality of speed-apart sectional tips in the lower end of said dust, having air-exits or notches formed between and in the edges of said sections facing the tip.

42. In a stove, the combination with a fuel-magazine, a pendant partition in said magazine, air-heating chambers, superheaters, two sets of tapered tubes communicating with said superheaters, one of said sets of tubes being arranged at an angle to the other, thus connecting the superheaters with the air-heating chambers, said tubes being provided

to deliver heated air to and through the bed of the fuel from the top, and means for delivering heated-air currents below the bed of the fuel.

43. In a stove, the combination with a fuel-magazine, a pendant partition therein, means for delivering a plurality of uniform currents of heated air to and through the fuel from the top, a series of tubes for delivering heated air below and through the bed of the fuel, and means for regulating the supply of air.

44. In a stove, the combination with a fuel-magazine, a pendant partition therein, means for delivering a plurality of heated-air currents to and through the fuel from the top, and a plurality of air-heating chambers having air-exits in rear of the pendant partition, said chambers being adapted to deliver currents of heated air to and through the fuel from the front and below the bed of the fuel.

45. In a stove the combination with a fuel-magazine, a pendant partition therein, means for delivering a plurality of heated-air currents to and through the fuel from the top, a plurality of air-heating chambers having air-exits on the side of the stove, and a plurality of tubes for delivering currents of heated air to and through the fuel from the front and below the bed of the fuel.

46. In a stove, the combination with a fuel-magazine, a pendant partition therein, means for delivering a plurality of heated-air currents to and through the fuel from the top, a plurality of air-heating chambers having air-exits in rear of the pendant partition, air-heating chambers having air-exits on the side of the stove, and a plurality of tubes for delivering currents of heated air to and through the fuel from the front and below the bed of the fuel.

47. In a stove, the combination with a fuel-magazine, a pendant perforated air-dust, speed-apart perforated tips in the lower end of said dust, an air-heating chamber, a flue or flues connecting said air-heating chamber and the air-dust, a second air-heating chamber and superheater, and means connected to said superheater for delivering a plurality of uniform currents of heated air to and through the fuel.

48. In a stove, the combination with a fuel-magazine, a pendant perforated air-dust, speed-apart perforated tips in the lower end of said dust, an air-heating chamber, a flue or flues connecting said air-heating chamber and the air-dust, a second air-heating chamber and superheater, and a plurality of tubes connected to said superheater, the tubes nearest the supply to the superheater being smaller than those remote therefrom for delivering uniform currents of heated air to and through the fuel.

49. In a stove, the combination with a fuel-magazine, a pendant perforated air-dust, speed-apart perforated tips in the lower end of said dust, an air-heating chamber, a flue or flues connecting said air-heating chamber and the air-dust, a second air-heating chamber and superheater, and a plurality of tapered tubes connected to said superheater, the tubes nearest the supply to the superheater being smaller than those remote therefrom, for delivering uniform currents of heated air to and through the fuel.

50. In a stove, the combination with a fuel-magazine, a pendant perforated air-dust, speed-apart perforated tips in the lower end of said dust, an air-heating chamber, a flue or flues connecting said air-heating chamber and the air-dust, an air-heating chamber and superheater depending from the stove-top, an additional air-heating chamber and superheater, the latter being arranged at an angle to the superheater nearest to the stove-top, tapered tubes projecting from the superheater, the tubes nearest the supply of air of one of the superheaters being smaller than those remote therefrom for delivering uniform currents of heated air to and through the fuel from the top, and a plurality of air-heating chambers having air-exits in rear of the air-dust for delivering currents of heated air to the rear of the fuel.

51. In a stove, the combination with a fuel-magazine, a flue, air-heating chambers, a superheater having air-exits, the air-heating chamber and superheater communicating, said superheater being positioned in the fuel-magazine to direct currents of heated air through the fuel-bed under the influence of the draft.

52. In a stove, the combination with a fuel-magazine, a flue, air-heating chambers, a superheater located in said fuel-magazine, thus connecting the air-heating chambers and the superheater, and a series of tubes projecting from said superheater, the exits of the tubes nearest the flue connecting the air-heating chambers being smaller than those remote therefrom.

53. In a stove, the combination with a fuel-magazine, an air-dust open at its lower end, tips secured within said lower open end of the dust, means for supplying heated air to said dust, of a fuel-door covering the fuel-opening of said magazine, air-heating chambers, a superheater attached to said fuel-door, flues connecting said air-heating chambers and said superheater when the fuel-door is closed, and means on the superheater for uniformly introducing currents of heated air to the fuel.

54. In a stove, the combination with a fuel-magazine, an air-dust in said magazine, covering the fuel-opening of said magazine, an air-dust in said magazine, said air-dust being provided with air-exits for delivering currents of heated air to the fuel, a superheater in said magazine, a series of tubes pro-

jecting from said superheater into the magazine, a second superheater attached to said fuel-door, tubes projecting from said superheater, means communicating with the superheater for supplying heated air thereto, and means for regulating the supply of air.

55. In a stove, the combination with a fuel-magazine, a flue, an air-dust, means in the lower end of said dust for distributing currents of heated air, air-heating chambers within said magazine, tubes projecting from said air-heating chambers being arranged at an angle to and at a point between a companion set of tubes projecting from a second air-heating chamber, said tubes projecting from said air-heating chambers being positioned to direct currents of heated air through the body of the fuel to the flue under the influence of the main draft.

56. In a stove, the combination with a fuel-magazine, a flue, an air-dust, means in the stove structure for applying heated air to said air-dust, and speed-apart tips in the lower end of said air-dust.

57. In a stove, the combination with a fuel-magazine, a flue, an air-heating chamber, a superheater communicating with said air-heating chamber, tubes projecting from the superheater into the fuel-magazine to direct currents of superheated air through the body of the fuel, an air-dust, an air-heating chamber which communicates with said air-dust, and means in the lower end of said dust for distributing currents of heated air to the body of the fuel.

58. In a down-draft-stove, the combination with a fuel-magazine, an air-dust, an air-dust in said magazine, an air-heating chamber, said chamber communicating with said air-dust, means secured within the lower end of the dust for distributing currents of heated air to the fuel, and a series of tapered tubes, constructed and arranged to deliver currents of air toward the bed of fuel whereby said latter currents of air, together with the heated-air currents delivered to the fuel from the means within the lower end of the air-dust, are drawn through the body of fuel under the influence of the draft.

59. In a stove, the combination with a fuel-magazine, air-heating chambers, a superheater, said superheater communicating with the air-heating chambers, a series of tubes projecting from said superheater, a second superheater, said second superheater communicating with the said air-heating chambers, tubes projecting from the second superheater and arranged at an angle to and approximately between the above-said series of tubes, a series of air-introducing tubes below the flue of the bed of the fuel, and means for regulating the supply of air introduced through said tubes.

60. In a stove, the combination with a fuel-magazine, a perforated air-dust, a flue, air-introducing tubes located above the bed of the fuel and adapted to direct currents of heated air through the body of the fuel, and a series of tubes below the bed of the fuel for introducing currents of heated air through the body of the fuel to mix therein with the currents of air introduced through the tubes from above.

61. In a down-draft-stove, the combination with a fuel-magazine, an air-dust in said fuel-magazine, air-heating chambers, a superheater, said superheater being in communication with the air-heating chambers, means for directing currents of superheated air from the superheater down upon or toward the top of the bed of the fuel and in front of the air-dust whereby said currents of superheated air are drawn through the fuel under the influence of the draft.

62. In a down-draft-stove, the combination with a fuel-magazine, an air-dust in said magazine, an air-dust in rear of said air-dust, air-heating chambers, a superheater arranged in front of the air-dust and communicating with said air-heating chambers, tubes projecting from said superheater toward the bed of fuel, and adapted to direct currents of heated air toward the bed of fuel for its combustion, said heated-air currents being drawn through the body of fuel from the top under the influence of the draft.

63. In a down-draft-stove, the combination with a fuel-magazine, an air-dust in said fuel-magazine, an air-dust in rear of said air-dust, air-heating chambers, a superheater which communicates with said air-heating chambers, means for uniformly and continuously delivering currents of superheated air from the superheater toward the top of the fuel-bed and in front of the air-dust, said superheated currents of air being drawn through the body of fuel under the influence of the draft.

64. In a down-draft-stove, the combination with a fuel-magazine, an air-dust, and a series of tubes arranged below the plane of the top of the bed of fuel and adapted to direct a series of individual currents of air toward the bed of fuel, said currents of air being drawn through the body of fuel under the influence of the draft.

65. In a stove, the combination with a fuel-magazine, an air-dust, a series of tubes located below the top of the bed of the fuel to direct a series of individual currents of air through the body of the fuel and a series of air-heating chambers provided with exits for introducing a plurality of heated-air currents to the fuel to mix therein, with the individual cur-

rents delivered from the tubes, the air-currents being drawn through the fuel under the influence of the draft.

66. In a down-draft-stove, the combination with a fuel-magazine, an air-dust, and a series of tapered tubes arranged below the plane of the top of the bed of fuel, and adapted to direct a series of individual currents of air toward the bed of fuel, said currents of air being drawn through the body of fuel under the influence of the draft.

67. In a down-draft-stove, the combination with a fuel-magazine, an air-dust, an air-dust in said magazine, means for delivering currents of superheated air toward the top of the bed of fuel in front of the air-dust, said currents of superheated air being drawn through the body of fuel under the influence of the draft.

68. In a stove, the combination with a fuel-magazine, a flue, an air-dust therein, air-heating chambers, a superheater, a series of tubes projecting from said superheater into the fuel-magazine, said superheater communicating with the air-heating chambers, a second superheater, means for delivering currents of superheated air to the fuel from said second superheater, the air-currents being drawn through the body of the fuel under the influence of the main draft.

69. In a stove, the combination with a fuel-magazine, air-heating chambers formed in the stove structure, superheaters communicating with said air-heating chambers, tubes projecting from said superheaters into the fuel-magazine for delivering currents of superheated air above the bed of the fuel, a series of tubes below the bed of the fuel for directing currents of heated air through the body of the fuel, and a series of air-heating chambers having a plurality of exits for introducing currents of heated air through the body of the fuel, said latter air-currents together with the air-currents introduced through the tubes located below the fuel-bed being drawn through the fuel-bed under the influence of the main draft.

70. In a down-draft-stove, the combination with a fuel-magazine, an air-dust, an air-heating chamber, a superheater communicating with said air-heating chamber, a series of tubes extending from said superheater and arranged to deliver currents of superheated air toward the bed of fuel, said superheated-air currents being drawn through the body of fuel under the influence of the draft.

71. In a down-draft-stove, the combination with a fuel-magazine, a flue, means for supplying individual currents of heated air to all sides of said magazine, and means for delivering a plurality of individual currents of heated air through the fuel from the top, all of said currents being drawn through the body of the fuel under the influence of the main draft.

72. In a stove, the combination with a fuel-magazine, a flue, means for heating air, a superheater, and a double series of tubes arranged intermediate each other for delivering individual currents of heated air through the flue from the top.

73. In a down-draft-stove, the combination with a fuel-magazine, an air-dust, an air-heating chamber, a series of tubes extending from said air-heating chamber, and arranged to deliver currents of heated air toward the bed of fuel, said heated-air currents being drawn through the bed of fuel under the influence of the draft.

74. In a down-draft-stove, the combination with a fuel-magazine, an air-dust communicating with the magazine near the bottom of the latter, an air-heating chamber, means for directing currents of heated air from said air-heating chamber toward the top of the bed of fuel, and means arranged below the plane of the top of the bed of fuel for delivering currents of heated air toward the fuel-bed, the currents of heated air which are delivered above the fuel-bed from the air-heating chamber, and the heated-air currents delivered toward the fuel-bed below the plane of the top, being drawn through the body of fuel under the influence of the draft.

698,800. STOVE. EDWIN H. GARDNER, Inventor, R. I. Filed Dec. 24, 1906. Serial No. 48,888. (No model.)

Claim.—1. In a stove, the combination of a fire-pot having an overhanging perforated portion, an air-dust, an air-heating chamber arranged to receive said fire-pot, means for regulating the admission of air to said air-heating chamber, a series of tubes entering the side walls of the fire-pot, each of said tubes having a window in its outer end and an opening in its inner side, heated air entering said tubes to be delivered to the body of the fuel from the sides thereof, heated air also being delivered downwardly to the top of the fuel-bed through the perforated overhanging portion of the fire-pot from the air-heating chamber; and means for delivering currents of heated air through the fuel from below, said air-currents being drawn in under the influence of the main draft, substantially as described.

2. In a stove, the combination with a fire-pot, an air-dust, an air-heating chamber surrounding said fire-pot, a series of tubes communicating with the air-heating chamber and the fire-pot for introducing heated air to the fuel-body from the sides thereof, an air-heating chamber above the fire-pot, and a portable sectional tube provided with air-exits at the meeting edges of said sections of the tube, said tube communicating with said

latter air-heating chamber to deliver air downwardly toward the fuel-bed in currents at various heights and angles to mix with the gases escaping to the flue, substantially as described.

3. In a stove, the combination of a fire-pot, an air-heating chamber, an exit-flue, an air-heating chamber surrounding said fire-pot, means for introducing air into said chamber, one or more tubes which enter the fire-pot, each tube having a perforation in its under side which communicates with the air-heating chamber, and means for introducing currents of heated air downwardly and at different levels toward the bed of the fuel which mixes with the gases escaping to the flue, substantially as described.

4. A stove comprising a casing, a fire-pot, means for introducing air to said fire-pot, an exit-flue, and a depending sectional tube provided with air-exits at the meeting ends of each section, said tube being located wholly above the top of the bed of the fuel and formed to deliver currents of air at different levels and angles to mix and ignite the gases escaping to the flue, substantially as described.

5. A stove comprising a casing, a fire-pot and a tube made in sections and loosely joined together, each section having a notched internal flange at its lower end and a notched turned-out flange at its upper end forming air-inlets, said flanges also forming the supports between the sections, substantially as described.

6. In a stove, the combination of a fire-pot made in two or more sections which overlap, said overlapping sections being provided with air-inlets, means for securing said sections together, and an air-heating chamber surrounding said fire-pot, for introducing air through said inlets, and means for introducing heated air downwardly toward the top of the fuel in the fire-pot, substantially as set forth.

7. In a stove, the combination of a fire-pot made in sections, means for securing said sections together, an air-heating chamber for delivering heated air above the bed of the fuel, means for introducing air to said chamber, an exit-flue, a covered air-heating chamber and a sectional tube communicating with said latter chamber, the meeting edges of said sections having exits to introduce currents of heated air downwardly and at different levels toward the fuel-bed, to mix and ignite the gases escaping to the flue, substantially as described.

8. A stove comprising a casing, a fire-pot made in sections, said sections overlapping and being provided with air-inlets, a passage being formed between the casing and fire-pot, regulating means for supplying air to said passage, a series of tubes entering the fire-pot, and a depending sectional tube provided with air-exits for delivering air to the top of the fuel, substantially as described.

9. A stove comprising a casing, a fire-pot, a perforated air-heating chamber surrounding said fire-pot, an overhanging upper ledge surrounding the chamber to deflect the air-currents to the top of the bed of the fuel, a series of tubes entering the fire-pot which communicate with said air-heating chamber, a second air-heating chamber, and a depending sectional tube communicating with said latter chamber, said tube having air-exits at the meeting ends of the sections to introduce currents of heated air downwardly at different levels toward the fuel-bed, substantially as described.

10. A stove comprising a casing, a fire-pot, a space being formed between said fire-pot and the casing, a portable sectional tube to supply

air at different levels above the bed of the fuel, an air-heating chamber above the fire-pot, an air-heating space being formed above said air-heating chamber, said space supplying air to the fire-pot and means for introducing air thereto, as set forth.

11. A stove comprising a casing, a fire-pot, an air-heating chamber in the stove structure, a depending sectional air introducing tube located wholly above the fuel-bed and communicating with said air-heating chamber, said sections having air-exits at the joints thereof, and means for flexibly joining the sections together, all for the purpose of delivering heated air currents above the fuel-bed at different angles and levels, substantially as described.

698,801. HEATING-STOVE. EDWIN R. VANCE, Newark, N. J.
Filed Mar. 5, 1901. Serial No. 49,512. (No model.)

Claim.—1. In a stove, the combination with a fire-pot, a grate, and means provided with individual openings for supporting the fire-pot, said fire-pot being constructed in sections, the lower section being made up of a series of pendant portable bars having means projecting from each bar which fit into one of the individual openings in the supporting means, substantially as set forth.

2. A stove comprising a casing, a grate, a fire-pot, said fire-pot being constructed in sections, the lower section being made up of a series of pendant portable weighted bars, and means provided with individual openings for supporting said bars, a hook on the rear of each bar which is adapted to fit in one of the individual openings of the support, and a flange on each bar below said hook to fit under a flange of the support, the lower weighted end of the bars fitting the lower flange of the bars in position substantially as set forth.

3. A stove comprising a casing, a grate, a fire-pot, said fire-pot being partly constructed of a series of portable pendant bars, a leg on each bar, a flange below said leg, a support provided with individual openings to accommodate said legs, said support being formed in said support for the flange of the bars, substantially as set forth.

4. A stove comprising a casing, a grate, a fire-pot, said fire-pot being partly constructed of a series of portable bars, means for supporting said bars, said means comprising a hook member and a flange below said member, and a supporting-ring said ring being provided with openings forming seats for the hook members and a bearing surface or support for the lower flange on the bars, substantially as set forth.

5. A stove comprising a casing, a grate, a fire-pot, said fire-pot being partly constructed of a series of portable bars, a support for said bars, and means on each bar which engage with the support whereby said portable bars have to be swung in or reeled toward the center of the stove and then lifted up, to disengage them for removal from which position they can be removed, substantially as set forth.

6. A stove comprising a casing, a grate, a fire-pot, said fire-pot be-

ing partly constructed of a series of pendant portable bars, and a support on which the bars are hung, each bar being provided with means wholly at the upper portion for engaging the support, and being held in position thereby by its free lower, weighted end, substantially as set forth.

7. A fire-pot constructed in sections, the lower section being made up of a series of pendant portable bars, means for supporting the bars, each bar being provided wholly at its upper portion with a device for engaging the means on which the bars are supported said device being held in locked proper position to the support by the weighted lower free end of said bars, substantially as set forth.

8. A stove comprising a casing, a grate, a fire-pot, said fire-pot being constructed in sections, the lower section being made up of a series of portable bars, an air-heating chamber surrounding said pot and said lower section of the fire-pot having openings which communicate with the air-heating chamber, means for supplying air to said air-heating chamber, and means on each pendant bar and the wall of the air-heating chamber for supporting said bars, substantially as set forth.

9. A stove comprising a casing, a grate, a fire-pot, the lower end of said fire-pot being composed of a series of pendant portable bars, an air-heating chamber surrounding the fire-pot, means on the air-heating chamber for supporting said bars, and means for supplying air to and distributing air from said chamber, substantially as set forth.

10. A stove comprising a casing, a grate, a fire-pot, the lower end of said fire-pot being composed of a series of pendant portable bars, an air-heating chamber having a series of exit-openings therein which surround the fire-pot, said air-heating chamber being made in sections and supporting the portable bars, and means for supplying air to said chamber, substantially as set forth.

11. A stove comprising a casing, a grate, a fire-pot, said fire-pot having its lower portion composed of a series of pendant portable bars, an air-heating chamber made in sections and surrounding said bars, each of said sections having coincident openings forming nests for the pendant bars and a series of air-exit openings, and means for supplying air to said chamber, substantially as set forth.

12. A stove comprising a casing, a fire-pot, a space being formed between said fire-pot and casing, a grate, and a series of combined air-introducers and air-exit openings communicating with said fire-pot at a point where the fuel becomes incandescent, said introducers communicating with the atmosphere and extending across the above-said space for heating the incoming air, substantially as and for the purpose specified.

13. A stove comprising a casing, a grate, a fire-pot, a series of combined air-introducers and air-exit openings communicating with the fire-pot at a point where the fuel becomes incandescent, double door having one of its panels of solid opaque formation and its other panel covered with a transparent material whereby the air-introducers may be either shut off entirely or the condition of the fuel may be exposed.

14. A stove comprising a casing, a grate, means for supporting said grate, a fire-pot constructed in sections the lower section of said fire-pot being made up of pendant portable bars, means for independently supporting said bars, an air-heating chamber having a series of air-exits surrounding the portable bars, a plate or flange on said chamber adapted to deflect the air-currents coming from the air-heating chamber through the air-exits toward the bed of the fuel, and means for supplying air to the air-chamber, substantially as set forth.

15. A stove comprising a casing, a grate, a fire-pot, the lower portion of said fire-pot being constructed of a series of pendant portable bars, an air-heating chamber surrounding said lower portion of the fire-pot, said air-heating chamber being made up of sections having exit-perforations and extensions, the extensions of the sections when placed together forming tubes for the introduction of air, and means for holding the portable bars, said means being provided with openings, and a series of legs below said openings on the lower section, substantially as set forth.

16. A stove comprising a casing, a grate, a fire-pot, said fire-pot being constructed in two sections the upper section being grooved vertically the grooves tapering from the top toward the bottom and the lower section being made up of a series of pendant portable bars, means for supporting the upper section, and means for supporting the pendant portable bars, substantially as set forth.

17. A stove comprising a casing, a grate, a fire-pot, said fire-pot being partly constructed of a series of pendant portable bars, each bar being weighted at the lower end, and means supporting said bars wholly at the upper portion, the lower ends of said bars being free when in place, substantially as set forth.

18. A stove comprising a casing, a grate, a fire-pot, said fire-pot composed of an upper member and a lower member made up of portable bars, a support intermediate the upper and lower members on which the upper member rests and, to which the bars forming the lower member hang, the lower free ends of the bars being free, a space being formed between the fire-pot and casing which communicates with the fire-pot through slots formed intermediate the bars, and a flue communicating with said space, substantially as set forth.

19. A stove comprising a casing a fire-pot having spaced pendant portable bars at the lower portion, a perforated air-heating chamber surrounding the upper ends of the bars and to which said bars are attached, radial flues opening to the atmosphere to supply air to said chamber, baffle-plates in one or more of said flues, a space being formed between the fire-pot and casing which communicates with said fire-pot at the lower end, a flue communicating with said space and means for delivering air downwardly through the flue, substantially as described.

20. A stove comprising a casing, a fire-pot made up of sections, an air-heating chamber interposed between said sections of the fire-pot, portable bars supported on said air-heating chamber which form the lower section of the fire-pot, a separate member seated on the air-heating chamber to support the upper section of the fire-pot, means for introducing air to the flue through the walls of the upper section, a space being formed between the fire-pot and casing and a flue communicating with said space, substantially as set forth.

21. A fire-pot comprising a series of portable pendant bars, each bar having outwardly-projecting means at its upper portion to fasten it in position, the lower ends being free, an air-heating chamber, means for supplying air to said chamber, individual openings in the lower wall of said chamber in which fit the outwardly-projecting means of the bars to fasten them in position, said openings being larger than the outwardly-projecting means of the bars forming air-exits, substantially as set forth.

22. A fire-pot comprising pendant portable bars, a support for the bars, said support being provided with a series of openings and a flange under said openings, and projections on each bar which coast with said openings and flanges when the parts are assembled, the projections being spaced in such relation to the support that the bars have to be moved in and up to be released, substantially as set forth.

23. A fire-pot comprising a support having openings, a flange on said support which is located under said openings, a series of, portable bars, each bar having a hook-shaped leg and a flange which is parallel with and is located under said leg, the upper end of said bar overhanging the leg while the lower end is free, substantially as set forth.

24. A fire-pot comprising upper and lower sections, the lower section being made up of a series of portable bars, an air-heating chamber intermediate the fire-pot sections which supports the fire-pot, means for supplying air to said chamber, a series of exits being formed in said chamber to deliver air to the fuel at different angles and levels, and a second series of exits being formed in the air-heating chamber for delivering currents of air to the escaping gases outside of the portable bars, substantially as set forth.

25. A fire-pot, comprising upper and lower sections, and an air-heating chamber interposed between and supporting said sections, means for supplying air to said air-heating chamber, a plurality of angularly-arranged exits being formed to introduce heated air at the juncture of the upper section of the fire-pot and the air-heating chamber, and a series of vertical exits being formed below said exits and outside the lower section to introduce heated-air currents to meet and mix with the escaping gases, substantially as described.

26. A fire-pot comprising upper and lower sections, the latter having a series of slots at the lower portion, an air-heating chamber, means for supplying air to said chamber, a series of exits being formed in the air-chamber to introduce currents of heated air to the fuel at different angles and levels, and two sets of exits being formed in the lower portion of the air-heating chamber to deliver currents of heated air downwardly and outside the lower section of the fire-pot to meet and mix with the escaping products of combustion, substantially as set forth.

27. A portable section for a fire-pot consisting of a head, the lower end of which is turned out, a hook-shaped leg also projecting outwardly from said head and above the outward end thereof, and a depending rounded portion extending from the head and provided with ribs and notches to form air-exits when two or more of said sections are assembled.

688,809. STOVE. EDWIN R. GANSON, Inventor, E. J. Fitch, Attor. 3, 1901. Serial No. 48,619. (No model.)

Claim.—1. A stove comprising a casing, a fire-pot, a magazine, and an independent packing connection where said is adapted to be varied at either edge when fitting it to overlap the shutting ends of said fire-pot and magazine substantially as described.

2. A stove comprising a casing, a fire-pot, a fuel-magazine having a depending overhanging lip projecting into said fire-pot, and an independent packing connection where said is adapted to be varied at either edge when fitting the shutting ends of the fire-pot and the fuel-magazine, substantially as described.

3. A stove comprising a casing, a fire-pot, a fuel-magazine, and a hinged independent packing connection where said is adapted to be varied at either edge when fitting the shutting ends of said fire-pot and fuel-magazine, substantially as described.

4. A stove comprising a casing, a fire-pot, a fuel-magazine, and a depending overhanging lip projecting into said fire-pot, and an independent packing connection between said fire-pot and the fuel-magazine, substantially as described.

5. A stove comprising a casing, a fire-pot, a fuel-magazine, an air-heating chamber interposed between the fuel-magazine and the fire-pot, said chamber having an upwardly-projecting flange or seat which forms a rest for the fuel-magazine, and an independent connection where said is adapted to be varied at either edge when fitting it to said fuel-magazine and the flange or seat on the air-heating chamber, substantially as described.

6. A stove comprising a casing, a fire-pot, a fuel-magazine, a supporting-ring in the upper end of said casing adapted to support the fuel-magazine, and an independent connection where said is adapted to be varied at either edge when fitting it to the fire-pot and the fuel-magazine, substantially as described.

7. A stove comprising a casing, a fuel-magazine, a fire-pot, one or more tubes for introducing air to the fuel in the fire-pot, means for supporting the tubes, movable air-heating chambers formed above the upper ends of the tubes and above the means for supporting said tubes, and plates connecting said chambers for covering the tubes when the chambers are moved, substantially as described.

8. A stove comprising a casing, a fuel-magazine, a fire-pot, one or more tubes for introducing air to the fuel in the fire-pot, means for supporting the tubes, and independent air-heating chambers formed above the upper end of each of the tubes and above the means for supporting said tubes, substantially as described.

9. A stove comprising a casing, a fuel-magazine, a fire-pot, a support fitted to the upper end of the casing and adapted to support the fuel-magazine, a top for said casing and magazine, one or more pipes or tubes depending from said top, and upwardly-extending flanges above said tubes to form air-heating chambers, substantially as described.

10. A stove comprising a casing, a fuel-magazine, a fire-pot, a support seated in the upper end of the casing having formed therein a stepped seat, one or more depending tubes, a support for holding said tubes, said support which is seated in the casing supporting both the fuel-magazine and the support from which the tubes depend, substantially as described.

11. A stove comprising a casing, a fuel-magazine, a fire-pot, a support seated in the upper end of the casing having formed therein a stepped seat, one or more depending tubes, a support for holding said tubes, a base having openings therein and surrounded by upwardly-extending flanges, which form continuations of the depending tube or tubes, and a stove-top composed of a lid portion and an outer portion surrounding said lid por-

tion, said latter portion having depending flanges adapted to abut with the upwardly-projecting flanges on the base, substantially as described.

12. A stove comprising a casing, a fuel-magazine, a fire-pot, one or more pipes or tubes adapted to deliver air to the fuel in the fire-pot, means for supporting said tubes, independent auxiliary air-heating chambers above and for each of said tubes, said chambers being formed above the upper open end of the tubes and above the support therefor, substantially as described.

13. In a stove, the combination of a fire-pot, one or more tubes adapted to deliver air to the fuel in the fire-pot, means for supporting said tubes with air, a cover over said means for supporting the tubes, auxiliary chambers located above the open ends of said tubes, said chambers being formed by flanges projecting above the means for supporting the tubes, and flanges projecting from the cover, substantially as described.

14. In a stove, the combination of a fire-pot, one or more tubes adapted to deliver air to the fuel in the fire-pot, a cover, supports for the tubes and movable auxiliary air-heating chambers located above and for each of the tubes for heating the air before entering said tubes, substantially as described.

15. In a stove, the combination of a fire-pot, a magazine, means for supporting the magazine, one or more tubes adapted to deliver air to the fuel in the fire-pot, a support for the tubes which is seated on the upper end of the magazine, and means for regulating the admission of air to the tubes, substantially as described.

16. A stove comprising a casing, a fire-pot having an upwardly-projecting flange, a magazine, and an independent packing connection where said is adapted to be varied at either edge when fitting it to the ends of the fire-pot and fuel-magazine, said packing connection being seated on the upwardly-projecting flange of said fire-pot, substantially as described.

17. A stove comprising a casing, a top, a fuel-magazine having a flange at its upper end, a fire-pot, a support mounted in the upper end of the casing having a seat formed at its inner edge, the flange of the magazine fitting the seat formed in the support thereby surrounding the magazine, a ring seated on the upper part of the magazine, a finishing-ring seated on the support on which the top rests, substantially as described.

18. A tube or tubes for the purpose specified, a support for the same, and means heated above the support to prevent the heat rising therefrom deflecting air entering said tubes, said means opening vertically to the atmosphere, substantially as described.

19. A downward-stove, comprising a casing, a fuel-magazine, a fire-pot, a support, tubes hung in the support, a cover, and independent auxiliary air-heating chambers located between the outer ends of the tubes and the cover, substantially as described.

20. A casing for a stove, and a top provided with flanges which extend from the upper and lower sides, the lower flange fitting the casing, an opening being formed for a fuel-door and a flange surrounding the same, a fuel-door, and a cover adapted to fit the flange on the upper side of the top of the stove and the flange surrounding the fuel-opening, substantially as described.

21. A stove comprising a casing, a stove-top having an opening surrounded by a flange, a fuel-magazine provided with a flange which fits the flange of the top, a fire-pot, and independent means connecting the magazine and fire-pot, where said is adapted to be varied at either edge when the magazine and fire-pot are placed in position, substantially as described.

698,808. STOVE. EDWIN R. GARDNER, Newark, N. J. Filed Mar. 4, 1901. Serial No. 48,324. (No model.)

Claim.—1. A stove comprising a casing, a fuel-chamber, a main exit-flue, a series of tubes for introducing jets of air through the fuel under the influence of the draft, a plurality of auxiliary flues communicating with each other at one end, and at their opposite ends with the main exit-flue, a damper in said flue to cut off the main exit-flue from the fuel-chamber to direct the products of combustion passing to the exit-flue through the plurality of auxiliary flues, an air-heating chamber interposed between the casing and the plurality of auxiliary flues, and flues connecting said chamber and the tubes as described.

2. A stove comprising a casing, a fuel-chamber, a main exit-flue, a series of tubes arranged to deliver jets of air below the bed of the fuel, a plurality of auxiliary flues communicating with each other at one end, and at their opposite ends with the main exit-flue, a damper in said flue to cut off the main exit-flue from the combustion-chamber to direct the products of combustion passing to the exit-flue through the plurality of auxiliary flues, a hot-air-supply chamber in proximity to the main exit-flue and the plurality of auxiliary flues, and means connected to said hot-air-chamber for supplying jets of heated air to the fuel-chamber, substantially as described.

3. A stove comprising a casing, a fuel-chamber, a main exit-flue, a plurality of auxiliary flues communicating with each other at one end, and at their opposite ends with the main exit-flue, a damper in said flue to cut off the main exit-flue from communication with the fuel-chamber to direct the products of combustion passing to the exit-flue through the plurality of auxiliary flues, a hot-air-supply chamber in proximity to the main exit-flue and the plurality of auxiliary flues, means connected to said hot-air-chamber for supplying a series of currents of heated air to the fuel-chamber in various places, and means also connected to the air-heating chamber for delivering jets of heated air to the fuel substantially as set forth.

4. A stove comprising a casing, a fuel-chamber, a main exit-flue, a hot-air-supply chamber, a superheater having perforated protuberances within the fuel-chamber, a hot-air-chamber communicating with said superheater, and flues connecting the hot-air-supply chamber and the hot-air-chamber communicating with the superheater, substantially as described.

5. A stove comprising a casing, a fuel-chamber, a pendant air-dust, a main exit-flue, a hot-air-supply chamber, flues connecting the hot-air-supply chamber and the air-dust, a superheater having perforated protuberances within the fuel-chamber, a hot-air-chamber communicating with said superheater, and flues connecting the hot-air-supply chamber and the hot-air-chamber communicating with the superheater, substantially as described.

6. A stove comprising a casing, a fuel-chamber, a pendant air-dust, a main exit-flue, a hot-air-supply chamber, flues connecting the hot-air-supply chamber and the air-dust, perforated hollow flanges in said fuel-chamber, flues connecting said hollow portions of said flanges with the hot-air-supply chamber, a superheater having perforated protuberances within the fuel-chamber, a hot-air-chamber communicating with said chamber, and flues connecting the hot-air-supply chamber and the hot-air-chamber communicating with the superheater, substantially as described.

7. A stove comprising a casing, a fuel-chamber, having a hollow lining, a pendant partition, a main exit-flue, a superheater having perforated protuberances, a damper in said superheater a hot-air-supply chamber, a damper for regulating the admission of air thereto, and pipes or flues leading from said chamber and communicating respectively with the air-dust, superheater and hollow lining, substantially as set forth.

8. A stove comprising a casing, a fuel-chamber, having a hollow lining, a pendant air-dust, provided with means for delivering currents of heated air to the fuel, a main exit-flue, a superheater having perforated protuberances, a hot-air-supply chamber located in the rear of the casing, and pipes or flues leading from said chamber and communicating respectively with the air-dust, superheater and hollow lining, a damper in the hot-air-supply chamber, and a damper in the superheater for independently controlling the air introduced through the perforated protuberances, substantially as set forth.

9. A stove comprising a casing, a fuel-chamber, a pendant air-dust, a main exit-flue, a plurality of auxiliary flues communicating with said exit-flue, a communicating-chamber at the bottom of said exit-flue with which said auxiliary flues communicate, a damper adapted to shut off direct communication between the central auxiliary flue and the main flue, to direct the products of combustion passing to the chimney to traverse the plurality of auxiliary flues, in combination with an air-heating chamber interposed between the casing and the flues and means co-operating therewith for delivering through the fuel-bed currents of heated air from the air-heating chamber, said air-currents being drawn through said fuel, under the influence of the draft.

10. A stove comprising a casing, a fuel-chamber, a pendant air-dust, a main exit-flue, a damper means coacting with said damper whereby the products of combustion are deflected and expanded and again brought together before said products of combustion leave the stove, in combination

with an air-heating chamber interposed between the casing and the flues, and means co-operating therewith for delivering through the fuel-bed currents of heated air from the air-heating chamber, said air-currents being drawn through said fuel under the influence of the draft.

11. A stove comprising a casing, a fuel-chamber, having a perforated hollow lining, a pendant air-dust, a main exit-flue, superheater, perforated hollow protuberances, a damper in said superheater, an air-heating supply-chamber, pipes or flues connecting said chamber with the hollow lining, the superheater and the air-dust, a plurality of auxiliary flues communicating with said main flue, a communicating-chamber at the bottom of said auxiliary flues, and a damper for cutting off the central auxiliary flue from direct communication with the main flue, substantially as described.

12. A stove comprising a casing, a fuel-magazine, an air-dust having openings in one of its walls, removable means in the lower end of said dust for distributing air to the fuel-magazine, said air-distributing means having flanges projecting beyond the air-dust, a shield supported at its lower end by said flanges on the means for distributing air, and hook-shaped lugs projecting from said shield and adapted to engage the openings in the air-dust, whereby said shield is prevented from being laterally displaced, except by an upward movement of the same, substantially as described.

13. A stove, comprising a casing, a fuel-magazine, a curved air-dust, a curved flue in rear of the same, an air-heating chamber positioned to be heated as the products pass through said flue, and means communicating with said chamber for delivering currents of heated air to the fuel.

14. A stove comprising a casing, a fuel-magazine, a chamber above the fuel, an air-dust, a flue in rear of the same for the escape of the products of combustion, said flue also connecting with the fuel-magazine, an air-heating chamber positioned to be heated as the products pass through said flue, and means communicating with said chamber for delivering two sets of currents of heated air to the fuel, one set of said currents of air being delivered to the air-chamber and thence to and through the fuel from the top, while the other set of air-currents are delivered to the air-dust and thence through the fuel from below the top.

698,804. HEATING-STOVE. EDWIN R. GARDNER, Newark, N. J. Filed Mar. 14, 1901. Serial No. 51,177. (No model.)

Claim.—1. A stove comprising a casing, a fire-pot, a magazine, said fire-pot having a series of pendant bars and lugs, flanges projecting from the casing for supporting said lugs, means for introducing air to a space between the magazine and fire-pot at a point where the products of combustion leave said fire-pot, and a hollow plate in said space having a damper therein for controlling the volume of heat, substantially as set forth for the purpose set forth.

2. A stove comprising a casing, a fire-pot, having a series of slots, a magazine, means for supporting the fire-pot and magazine, an air-heating chamber having air-exits formed between the fire-pot and magazine, means for supplying air to said chamber, means for introducing air to the space formed between the fire-pot and casing, an exit-flue communicating with said space at the upper end, and means for controlling the volume of heat.

3. A stove comprising a casing, a fire-pot having a series of depending bars and having a series of corresponding slots between said bars, a magazine, an air-heating chamber having air-exits between the fire-pot and magazine, means for supplying air to said chamber, means for supplying the space formed between the fire-pot and casing with air, an exit-flue communicating with said space, tubes for introducing air to the body of fuel from the sides, and tubes for delivering currents of air downwardly through the fuel.

4. A stove, comprising a casing, a fire-pot, having a series of depend-

ing base and having spaces formed therebetween, legs projecting from the fire-pot, flanges for supporting said legs, an exit-flue communicating with the space formed between the fire-pot and casing, tubes adapted to deliver air downwardly through the fuel, and means communicating at the upper end with the magazine, and at the lower end with the fire-pot below the top of the bed of the fuel, whereby air may be supplied to the fire-pot from the top if the fuel becomes packed.

5. A stove comprising a casing, a fire-pot provided with a surrounding air-heating chamber, a space being formed between the fire-pot, magazine and casing, an exit-flue communicating with said space, a baffle-plate in the space which inclines upwardly toward the front and provided with an opening and a damper, and means for delivering currents of air downwardly through the fuel under the influence of the draft.

898,805: STOVE-LINING. EDWIN R. GARDNER, Newark, N. J.
Original application filed Dec. 14, 1902, Serial No. 746,313. Divided and this application filed Mar. 14, 1904. Serial No. 61,490. (No model.)

Claim.—1. A fire-pot lining comprising a series of portable sections, each section having a leg on one side and a notch on its opposite side, and an outwardly-projecting flange on each side one of which is wider than the other, the leg of one section fitting the notch of the adjoining section, and the widest flange of one section overlapping the narrow flange of the adjoining section thereby locking and positioning the sections together when assembled.

2. A fire-pot lining comprising a series of portable sections, each section having a front portion and a base spaced from each other, said base having its edges notched, one side of said base extending beyond the line of the edge of the front portion and adapted to overlap the base of an adjoining section, the notches in the base registering to form air-channels, whereby air may be introduced to the fire-pot, means for spacing apart the front portions of the adjoining sections, and means for securing the sections together.

3. A fire-pot lining comprising a series of portable sections, each section having a front portion and a base, means connecting the front portion and base, the front portion, the base and the means connecting the same form, with adjoining sections, when assembled air-chambers, and a head which is slightly wider than the front portion whereby a space is formed between two adjoining sections below the head to form exits for air to pass to the fire-pot, air-heating chambers communicating with said space, and means for holding the sections together.

4. A section for a fire-pot lining, comprising a front portion, a base, and a web connecting the front portion and base, said base being provided with notches along its side edges adapted to be brought into alignment with notches of adjacent sections of a fire-pot, said section also comprising means for spacing it from adjacent sections and from the fire-pot, whereby air may be heated and introduced into the combustion-chamber through the spaces formed between adjacent sections when assembled.

5. A fire-pot lining, comprising portable sections, having a front portion, a base having its edges notched, and a web connecting the front portion and base, air-heating chambers being formed between the sections when placed side by side, means for spacing the sections, to form exits from said chambers, and air-heating chambers also being formed between the fire-pot and portable sections, said air-heating chambers communicating through the notches in the base with the adjacent air-heating chambers formed between the adjoining sections.

898,806. HEATING-STOVE. EDWIN R. GARDNER, Newark, N. J.
Filed July 11, 1901. Serial No. 67,982. (No model.)

Claim.—1. A downdraft-stove comprising a casing, a fire-pot, an air-heating chamber or chambers arranged at the top of the stove to receive the ascending heated air surrounding the stove, means for directing the air to said chamber or chambers, and means communicating with said chamber for delivering said heated air downwardly in individual currents to the fuel from which the gases are generated, said heated air being drawn through the fuel under the influence of the draft.

2. A stove comprising a casing, a fire-pot, an air-heating chamber in proximity to the fire-pot, auxiliary air-heating chambers, means connecting the chamber in proximity to the fire-pot and the auxiliary air-heating chambers, a second set of auxiliary chambers, and tubes depending therefrom toward the bed of the fuel to direct currents of heated air therethrough.

3. A stove comprising a casing, a fire-pot, an air-heating chamber in proximity to said fire-pot, auxiliary air-heating chambers, a deflector adapted to deflect the ascending heated air surrounding the stove to said chambers and toward the fuel to direct currents of heated air through the fuel-bed.

4. A stove comprising a casing, a fire-pot, a space being formed between said casing and fire-pot, a flue communicating with the aforesaid space, an air-heating chamber in proximity to said fire-pot, auxiliary air-heating chambers, ducts connecting said latter air-heating chambers and the air-heating chamber in proximity to the fire-pot, said ducts being located between the casing and the fire-pot in the path of the gases coming to the exit-flue.

5. A stove comprising a casing, a fire-pot, a flue, an air-heating chamber arranged to deliver currents of heated air to the fuel, two sets of auxiliary air-heating chambers, means for supplying one set of auxiliary air-heating chambers with the ascending heated air which surrounds the stove, tubes depending from said chambers to deliver currents of air through the fuel from the top, the second set of auxiliary chambers being supplied with air from the top, and ducts connecting said latter auxiliary air-heating chambers with the said air-heating chamber which surrounds the fire-pot.

6. A heating-stove comprising a casing, a fire-pot, a flue, a perforated air-heating chamber in proximity to and surrounding the fire-pot, two sets of auxiliary air-heating chambers in the stove-top, deflector arranged to deliver air to one end of said chambers, means connected to said chamber for delivering heated-air currents downwardly through the fuel, the second set of auxiliary chambers being supplied with air from the top, and ducts connecting said latter chambers with the air-heating chamber heated in proximity to the fire-pot.

7. A stove, comprising a casing, a fire-pot, a main flue, air-heating chambers arranged to receive the ascending heat surrounding the stove, a space being formed between the fire-pot and drum, a drum, an auxiliary flue in said space, said flue being connected at both ends with the main exit-flue, and a damper adapted to direct the escaping gases either to the main flue or the auxiliary flue.

8. A downdraft-stove, a drum comprising a casing, a fire-pot, a main exit-flue, air-heating chamber or chambers arranged to receive the ascending heat surrounding the stove, a space being formed between the casing and the drum, an auxiliary flue in said space one end of said flue being

positioned to receive the escaping products of combustion and its opposite end in communication with the main-exit-flue, and a damper adapted to direct the escaping gases either to the main flue or the auxiliary flue.

9. A downdraft-stove comprising a casing, a fire-pot, air-heating chamber or chambers arranged at or near the top of the stove to receive the ascending heated air surrounding the stove, means for deflecting said ascending heated air to said chamber or chambers, and tubes extending from said chamber or chambers for delivering heated air downwardly in individual currents to the fuel, from which the gases are generated, said heated air being drawn through the fuel under the influence of the draft.

10. A downdraft-stove comprising a casing, a fire-pot, air-heating chamber or chambers arranged at the top of the stove to receive the ascending heated air surrounding the stove, an air-heating chamber in proximity to the fire-pot, means of communication between said chamber or chambers and the air-heating chamber surrounding said fire-pot, whereby currents of heated air are delivered to the fuel, said currents of air being drawn through the bed of fuel under the influence of the draft.

11. In a downdraft-stove, the combination with a casing, a fire-pot, an exit-flue, air-heating chamber or chambers arranged at or near the top of the stove to receive the ascending heated air which surrounds the stove, means for deflecting the said heated air to the chamber, and tubes extending from said chamber or chambers for delivering heated air to the fuel, said heated air being drawn through the fuel under the influence of the draft.

12. In a downdraft-stove, the combination with a casing, a fire-pot, air-heating chamber arranged to receive the ascending heat surrounding the stove, an air-heating chamber surrounding the fire-pot, means connecting the chamber which receives the ascending heated air and the chamber which surrounds the fire-pot, whereby the ascending heat is preheated and delivered to the fuel, said air being drawn through the fuel under the influence of the draft, a drum, and an exit-flue located between the casing, and drum, whereby the ascending air is heated.

13. In a downdraft-stove, the combination with a casing, a fire-pot, an exit-flue, air-heating chamber adapted to receive the ascending heated air which surrounds the stove, said air being delivered to the fuel through openings in the chamber, and drawn through the fuel-bed under the influence of the draft, a drum, a chamber, flues connecting said chamber, and a space between the fire-pot and casing, and means for directing the escaping gases through the said flues and chamber, or direct through the exit-flue.

14. In a stove, the combination with a casing, a fire-pot, an exit-flue, an air-heating chamber having openings surrounding the fire-pot and adapted to deliver air to the fuel, means for deflecting the ascending heated air which surrounds the stove to the air-heating chamber in the fire-pot, means for delivering heated air to the fuel from the top, and a series of tubes for delivering a plurality of air-currents to the fuel intermediate the air-currents delivered from the top and the currents of air delivered from the air-heating chamber in the fire-pot.

15. In a downdraft-stove, the combination with a casing, a fire-pot, an exit-flue, an air-heating chamber having openings surrounding the fire-pot, and adapted to deliver air to the fuel, means for deflecting the ascending heated air which surrounds the stove to the air-heating chamber in the fire-pot, means for delivering heated air to the fuel from the top, and a series of tubes for delivering a plurality of air-currents to the fuel intermediate the air-currents delivered from the top, and the currents of air delivered from the air-heating chamber in the fire-pot, all of said currents of air being drawn through the fuel under the influence of the draft.

16. In a downdraft-stove, the combination with a casing, a fire-pot, an exit-flue, an air-heating chamber arranged to deliver currents of heated air to the fuel, two sets of auxiliary air-heating chambers, means for supplying one set of auxiliary air-heating chambers with heated air, tubes depending from said chambers to deliver currents of air to the fuel, the second set of auxiliary chambers communicating direct with the atmosphere, ducts connecting said second set of auxiliary chambers with the first-named air-heating chamber, the two sets of currents of air delivered to the fuel from the latter chamber, and from the tubes, being drawn through the fuel under the influence of the draft.

17. In a downdraft-stove the combination with a casing, a fire-pot, an exit-flue, a plurality of air-heating chambers arranged at or near the top of the stove to receive the ascending heated air which surrounds the stove, means arranged adjacent the fire-pot for preheating the air and delivering said air to the fuel and means communicating with said chambers and the means for preheating the air, the heated air being drawn through the fuel under the influence of the draft.

18. In a downdraft-stove, comprising a fire-pot, an air-heating chamber from which heated air is delivered to the fuel, auxiliary air-heating chambers, means connecting the air-heating chamber and the auxiliary air-heating chambers, a second set of auxiliary chambers, having openings through which currents of heated air are directed to the fuel, said latter currents of heated air and the air delivered to the fuel from the first-

named air-heating chamber being drawn through the fuel under the influence of the draft.

19. In a downdraft-stove, the combination with a casing, a fire-pot, auxiliary air-heating chambers at or near the top of the stove, means for gathering and deflecting into the auxiliary chambers the ascending heated air which surrounds the stove, an air-heating chamber having a series of openings to deliver heated-air currents to the fuel, means connecting the latter air-heating chamber and the auxiliary air-heating chambers, the air-currents from the air-heating chamber being drawn through the fuel under the influence of the draft.

20. In a downdraft-stove, the combination with a casing, a fire-pot, an exit-flue, auxiliary air-heating chambers at or near the top of the stove, an air-heating chamber surrounding the fire-pot and having a series of exit-openings to direct currents of air to the fuel, and ducts connecting the auxiliary air-heating chambers and the air-heating chamber which surrounds the fire-pot, said ducts being heated to be heated by the heat in the fire-pot, the heated-air currents delivered to the fuel being drawn through the fuel-bed under the influence of the draft.

21. In a downdraft-stove, the combination with a casing, a fire-pot, an exit-flue, air-heating chambers arranged to receive the ascending heated air surrounding the stove, means communicating with the said air-heating chambers for delivering heated-air currents to the fuel, and a series of tubes communicating with the atmosphere for delivering a plurality of air-currents to the fuel independent of the heated-air currents delivered from the air-heating chambers, all of said currents of air being drawn through the fuel under the influence of the draft.

22. In a downdraft-stove, the combination with a casing, a fire-pot, a space being formed between the casing and the fire-pot, an exit-flue communicating with said space, a drum spaced from the casing, tubes entering the fire-pot and communicating with the atmosphere, the air entering said tubes being heated by the ascending heated air in the space formed between the drum and the casing, and the space between the fire-pot, and casing, air-heating chambers arranged to receive the ascending heated air which surrounds the stove means communicating with said air-heating chambers for delivering currents of preheated air to the fuel, all of the aforesaid currents of heated air being drawn through the fuel under the influence of the draft.

698,807. POKER-SUPPORT. EDWIN R. GANNON, Newark, N. J.
Original application filed Feb. 4, 1897, Serial No. 681,804. Divided and this application filed Nov. 19, 1901. Serial No. 62,948. (No model.)

Claim.—1. A means for supporting a poker on a stove, comprising an upper flange provided with a counterbore perforation, and a lower flange having an opening therein approximately under the perforation in the upper flange to form a guide for the lower end of the poker, substantially as shown and described.

2. A means for supporting a poker on a stove, comprising an upper flange provided with a counterbore perforation, and a lower flange having a guide therein to receive the lower end of the poker, substantially as shown and described.

3. A means for supporting a poker on a stove, comprising an upper flange provided with a bevel perforation, and a lower flange having an opening therein which is larger than the opening in the upper flange, substantially as shown and described.

4. A means for supporting a poker on a stove, comprising an upper flange provided with a bevel perforation, and a lower flange having an elongated opening therein approximately under the bevel perforation in the upper flange, substantially as shown and described.

10. A means for supporting a poker on a stove, comprising an upper flange provided with a perforation, and a lower flange having a perforation which is larger than the perforation in the upper flange to form a guide for the lower end of the poker, substantially as described.

698,808. MECHANISM FOR OPERATING DAMPERS. EDWIN R. GARDNER, Troy, N. Y. Original application filed Mar. 5, 1891, Serial No. 69,810. Divided and this application filed Jan. 12, 1902. Serial No. 59,592. (No model.)

Claim.—1. In a down-draft-stove, the combination with a casing, a fire-pot having an opening at or near its upper end, and a gravity-damper normally covering said opening, an exit-space being formed between the fire-pot and casing, an exit-flue, a feed-door and a connection between said door and the damper, whereby the damper is uncovered when the feed-door is raised, and communication formed direct with the exit-flue and the fire-pot, said damper closing by gravity when the feed-door is closed, substantially as described.

2. A device for the purpose described, comprising a damper adapted to be swung upwardly, a hinged door, and means connecting the door and damper whereby said damper is opened when the door is opened, and closes by gravity when the door is closed, substantially as described.

3. In a stove, the combination with a casing, a cover, a damper having legs, bearings which are open adjacent the cover, said legs being confined by the cover, a feed-door, and means connecting the feed-door and damper, whereby the two are simultaneously operated.

4. In a down-draft-stove, the combination with a casing, a top, a feed-door in said top, a fire-pot having an opening at or near its upper end, a damper normally covering said opening, means connecting the damper and feed door, and a swinging cap, said cap contacting with the feed-door to open the damper, substantially as described.

5. A horizontal swinging member, a door opening at an angle thereto, in combination with a damper, and a connection between the damper and said door whereby the damper is operated when the horizontal swinging member is operated, substantially as described.

6. A horizontal swinging member, a door opening at an angle thereto, in combination with a hinged damper, and a chain connecting the damper and said door, whereby the damper is elevated when the horizontal swinging member is operated, substantially as described.

7. In a down-draft-stove, the combination with a casing, a fire-pot having an opening at or near the top, bearings which are open at the top, a damper provided with legs which are seated in said bearings, a top, said top confining the legs of the damper in the bearings, a door in the top, and a connection between the door and damper, whereby the damper and door are simultaneously operated, substantially as described.

8. In a down-draft-stove, the combination with a casing, a fire-pot having an opening, a damper covering said opening, an exit-space being formed between the fire-pot and casing, an exit-flue communicating with said exit-space, a feed-door, and a connection between said door and the damper, said connection being a chain, whereby the damper uncovers the opening in the fire-pot when the feed-door is opened, and may be seated independent of the feed-door, substantially as described.

698,809. AIR-INTRODUCER FOR STOVE. EDWIN R. GARDNER, Troy, N. Y. Original application filed Mar. 5, 1891, Serial No. 69,811. Divided and this application filed Jan. 14, 1902. Serial No. 59,593. (No model.)

Claim.—1. In a stove the combination with a casing having one or more openings, a fire-pot, an air-introducer or introducers registering with the opening or openings in the casing each introducer comprising a frame which is open at its receiving and exit ends, a jacket surrounding said frame forming a passage intermediate the two, said passage communicating with the interior of the frame at or near the receiving end of the latter, and at its opposite end with the atmosphere.

2. The combination with a stove-casing having an opening, and an air-introducer registering with said opening, said introducer comprising a frame which is open at its receiving and exit ends, a jacket surrounding the frame, a passage being formed intermediate the frame and the jacket, openings for admitting air to the passage, openings located at the opposite end of the frame for admitting air from the passage to the interior of the frame, and means in the frame for breaking the air, substantially as described.

3. The combination with a stove-casing having an opening therein, an air-introducer registering with said opening, said introducer comprising an open frame having a plurality of notches at one end, means in the frame for breaking air, said means being displaced from either end of the open frame, a jacket surrounding the frame, a space being formed intermediate the frame and the jacket, and a plurality of air-inlets formed in the jacket at or near the base thereof to introduce air to the space, substantially as described.

4. The combination with a stove-casing having an opening therein, an air-introducer registering with said opening, said introducer comprising an open frame having a plurality of notches at one end, means in the frame for breaking air, said means being displaced from either end of the open frame, a jacket surrounding the frame, a space being formed intermediate the frame and the jacket, and a series of notches in the jacket to admit air at or near the end of the space opposite to that of the notches in the open frame, substantially as described.

5. The combination with a stove-casing having one or a plurality of openings, air-introducers registering with the openings, each introducer comprising an open frame registering with one of the openings in the casing, a flange on the frame which is on the inner side of the casing, means for covering the flange in position, a jacket surrounding the frame, a space being formed between the two, openings being formed for the introduction of air to the space, at or near one end, and openings being formed at or near the opposite end of the space, for the introduction of air from said space to the interior of the frame, substantially as described.

6. The combination with a stove-casing having a plurality of openings, air-introducers registering with the openings, each introducer comprising an open frame which registers with one of the openings in the casing, a flange on the frame which is located on the inner side of the casing, means for spacing the flange from the casing, means for covering the flange in position, a jacket surrounding the frame, a space being formed between the jacket and frame, openings communicating with the space for the introduction of air thereto.

7. An air-introducer comprising an open frame, a jacket surrounding the frame, a removable cover on the jacket, means for covering the jacket in position, a space being formed intermediate the frame and jacket, openings being formed in the jacket to admit air to said space at or near one end thereof, said space communicating at or near its opposite end with the interior of the open frame, and means in the interior of, and displaced from either end of the frame to break the air, substantially as described.

8. An air-introducer comprising a frame open at its receiving and exit ends and tapering toward its receiving end, means in the frame for breaking air, a jacket larger than the frame and surrounding the latter, forming a space intermediate the frame and the jacket, said space communicating with the atmosphere at one end and the interior of the frame at the opposite end, substantially as described.

9. The combination with a stove-casing having openings therein, air-introducers registering with the openings, a flange extending from each introducer and placed on the inside of the casing, a space being formed intermediate the flange and casing, a lock for fastening said flange, legs extending from the lock which embrace the flange, and a nut being formed to position the lock, substantially as described.

10. An air-introducer comprising an open frame, having a plurality of notches at its outer end, a piece of sheet-metal mounted in the interior of the frame, a transparent cover fitted over the outer end of the frame, a jacket surrounding the frame, a series of inlets being formed at the inner end of the jacket, and a space being formed intermediate the jacket and casing whereby air is introduced to the passage, thence to the interior of the frame, substantially as described.

11. In a down-draft-stove, the combination with a fire-pot, a casing having a plurality of openings adjacent the fire-pot, a space being formed intermediate the fire-pot and casing, air-introducers registering with the openings, each introducer comprising an open frame, a jacket surrounding the frame, a space being formed intermediate the two, means for introducing air to the space, openings being formed between the space and the interior of the open frame, and means for breaking the air, whereby a plurality of finely-divided heated-air currents are delivered to the products of combustion in the latter lower the fire-pot, substantially as described.

12. The combination with a stove-casing having an opening therein, an air-introducer registering with said opening, said introducer comprising an open frame having air-inlets at or near one end, means in the frame for breaking air, a jacket surrounding the frame, a space being formed intermediate the frame and the jacket, and a plurality of air-inlets formed in the jacket at or near the opposite end of the space, substantially as described.

13. The combination with a stove-casing having an opening therein, an air-introducer comprising a frame having a passage therein, inlets being formed for admitting air to said passage, an exit-opening being formed for the escape of air into the interior of the frame, a flange extending from the introducer and being located within the casing and a space being formed intermediate the flange and casing, substantially as described.

698,810. HEATING-STOVE. EDWIN R. GARDNER, Troy, N. Y. Original application filed Mar. 5, 1891, Serial No. 69,812. Divided and this application filed Jan. 22, 1902. Serial No. 59,594. (No model.)

Claim.—1. A down-draft-stove comprising a casing, a fire-pot provided with a series of air-pockets, detachable covers for said pockets having slots whereby fuel is prevented falling into the pockets and the free ingress and egress of the air to the fuel is not retarded, and means for covering the covers in position, substantially as described.

2. A down-draft-stove comprising a casing, a fire-pot provided with

a series of air-pockets, detachable covers for said pockets which are open at the lower ends, whereby the ingress and egress of air to the fuel is permitted, and means for covering the covers in position, substantially as described.

3. A down-draft-stove comprising a casing, a fire-pot having a series of pockets, covers for said pockets which are raised at their lower ends, seats for the raised ends, and means for locking the covers in position, whereby the admission of air to the fuel is not retarded, substantially as described.

4. A down-draft-stove comprising a casing, a fire-pot, means for introducing currents of preheated air downwardly to the fuel in the fire-pot, said air being drawn through the fuel under the influence of the draft, a plurality of air-pockets in the fire-pot, a space being formed intermediate the fire-pot and casing which communicates with the lower end of the fire-pot, an exit-flue communicating with the space at or near the top of the latter and a damper in the upper part of the fire-pot at or near the exit-flue, substantially as described.

5. In a down-draft-stove, the combination with a casing, a fire-pot which is provided with a plurality of air-pockets, detachable covers for said air-pockets, a series of air-introducers in the fire-pot below said pockets and at a point where the fuel is inaccessibly, substantially as described.

6. In a down-draft-stove, the combination with a casing, a fire-pot which is provided with one or more air-pockets, air-introducers located above the bed of the fuel, and a series of air-introducers in the fire-pot at a point below the top of the bed of the fuel where the latter is inaccessible, substantially as described.

7. In a down-draft-stove, the combination with a casing, a fire-pot which is provided with a series of air-pockets, a damper at or near the top of the fire-pot, detachable covers for the pockets, product portable bars having cut-spaces therebetween forming the bottom of the fire-pot, a space being formed intermediate the fire-pot and casing which communicates with the fire-pot through the spaces between the product portable bars and an exit-flue communicating with the space at or near the top, substantially as described.

8. In a down-draft-stove, the combination with a casing, a fire-pot made in sections, the lower section being constructed of product portable bars, means for independently supporting said bars, an air-heating chamber having a series of air-cuts surrounding the portable bars, a plate or flange adapted to deflect the air-currents coming from the air-heating chamber toward the bed of fuel, means for supplying air to the air-heating chamber, the upper section of the fire-pot resting on the plate or flange and being provided with a series of air-pockets, and means at or near the top of the stove for introducing currents of heated air, substantially as described.

9. A down-draft-stove comprising a casing, a fire-pot made in sections, the lower section being made up of product portable bars, a space being formed between the casing and fire-pot, an air-heating chamber surrounding the portable bars, a plate or flange which supports the upper section of the fire-pot, pockets being formed in said upper section, a damper above the air-pockets, means for introducing currents of heated air above the bed of the fuel, and an exit-flue communicating with the space at or near the top, substantially as described.

10. In a down-draft-stove, the combination with a casing, a fire-pot having a series of openings at its lower end, a space being formed intermediate the fire-pot and casing, a damper at or near the top of the fire-pot, an exit-flue communicating with the space at or near the top, means for introducing individual currents of heated air downwardly to the fuel, and means for introducing currents of air into the inaccessibly mass of fuel from the sides, said air being drawn through the fuel under the influence of the draft, substantially as described.

11. In a down-draft-stove, the combination with a casing, a fire-pot having a series of openings at its lower end which communicates with an exit-space formed intermediate the fire-pot and casing, a perforated air-heating chamber forming a part of the fire-pot structure, a water-jacket surrounding the outside of the fire-pot, said water-jacket being above and in close relation to the air-chamber, an exit-flue communicating with the space at or near the top thereof, and means for introducing currents of heated air to the top of the fuel, said air-currents being drawn through the fuel under the influence of the draft.

12. In a down-draft-stove, the combination with a casing, a fire-pot, having a series of slots at the bottom which communicates with a space intermediate the fire-pot and casing, an air-heating chamber having air-cuts surrounding the fire-pot, means for introducing air to said chamber, means for deflecting heated currents of air coming from the chamber toward the center of the fuel, and means for introducing currents of heated air above the fuel, all of said air-currents being drawn through the fuel under the influence of the draft, substantially as described.

13. In a down-draft-stove, the combination with a casing, a fire-pot having a series of openings at its lower end which communicates with a space intermediate the casing and fire-pot, an air-heating chamber in the

space, said chamber having a series of air-exits to introduce heated air to the fuel, means for introducing air to the air-heating chamber, and means for introducing currents of heated air above the fuel, all of said air-currents being drawn through the fuel under the influence of the draft.

14. In a downdraft-stove, the combination with a casing, a fire-pot having a series of openings at the bottom which communicate with a space intermediate the casing and fire-pot, an exit-flue communicating with said space, an air-heating chamber having air-exits surrounding the fire-pot, means for supporting the air-heating chamber in the space, the lower wall of said chamber forming a portion of the fire-pot, means for introducing air to the air-heating chamber, and means for introducing currents of heated air above the fuel, the air-currents being drawn through the fuel under the influence of the draft, substantially as described.

15. In a downdraft-stove, the combination with a casing, a fire-pot, an exit-flue, an air-heating chamber surrounding the fire-pot which has a series of air-exits, means for introducing air to said chamber, means for introducing air in individual currents to the body of the fuel, and means for delivering individual currents of heated air at different levels to the top of the bed of the fuel, all of said air-currents being drawn through the fuel under the influence of the draft, substantially as described.

16. In a downdraft-stove, the combination with a casing, a fire-pot having a series of openings at its lower and which communicate with a space formed intermediate the casing and fire-pot, an exit-flue, an air-heating chamber mounted in said space, means for supplying air to the chamber, and a series of exit-openings being formed in the chamber at different angles and of different sizes to deliver air-currents at various points to the fuel at varying angles and proportions, said air-currents being drawn through the fuel under the influence of the draft, substantially as described.

17. In a downdraft-stove, the combination with a casing, a fire-pot, an exit-flue, an air-heating chamber having air-exits surrounding the fire-pot, an air-heating chamber, ducts connecting with said air-heating chamber to deliver heated air above the fuel, and means permitting the passage of the heated air should the mass of fuel become packed, substantially as described.

18. In a downdraft-stove, the combination with a casing, a fire-pot, an exit-flue, means for introducing individual currents of air to the top of the fuel, means for introducing individual currents of air to the fuel below the top thereof, a passage or passages being formed on the interior of the fire-pot to permit the air to pass on the outside of the fuel, openings being formed for the escape of the air from the passage or passages to the fuel, said air together with the individual currents being drawn down through the fuel under the influence of the draft, substantially as described.

19. In a downdraft-stove, the combination with a casing, a fire-pot having a series of openings at the lower and which communicate with a space formed intermediate the casing and fire-pot, a flue communicating with said space, an air-heating chamber surrounding the fire-pot, a series of air-exits being formed therein to introduce air to the fuel, means for introducing air to the fuel from the top, and means for introducing finely-divided air-currents to the products of combustion when the latter leave the fire-pot to enter the space, all of the air-currents being drawn through the fuel under the influence of the draft, substantially as described.

20. In a downdraft-stove, the combination with a fire-pot, means for introducing currents of heated air to the top of the fuel, means for introducing heated air to the sides of the fuel, means for introducing heated air intermediate the two aforesaid means, and a series of air-pockets in the fire-pot, substantially as described.

21. In a downdraft-stove, the combination with a casing, a fire-pot, made in sections, the lower section being constructed of pendant portable bars, means for independently supporting said bars, an air-heating chamber having a series of air-exits surrounding the portable bars, means for deflecting part of the air-currents coming from the air-heating chamber toward the bed of fuel, means for supplying air to the air-heating chamber, the upper section of the fire-pot resting on the means for deflecting a part of the air, air-pockets, and means at or near the top of the stove for introducing currents of heated air, substantially as described.

22. In a downdraft-stove, the combination with a casing, a fire-pot having a series of openings at the lower and which communicate with a space formed intermediate the casing and fire-pot, an air-heating chamber in the fire-pot, having a series of air-openings to introduce heated air to the fuel, means for introducing individual currents of heated air to the top of the fuel, means for introducing currents of heated air intermediate the means for delivering air to the top of the fuel and the series of openings at the lower end of the fire-pot, the air-currents being drawn through the fuel under the influence of the draft, and means for introducing finely-divided air-currents to the products of combustion after the latter leave the fire-pot.

23. In a downdraft-stove, the combination with a casing, a fire-pot, which is provided with one or more air-pockets, air-introducers heated

above the air-pockets and the bed of fuel and adjacent the walls of the fire-pot, and a series of air-introducers in the fire-pot at a point below the top of the bed of the fuel where the latter is incandescent.

24. In a downdraft-stove, the combination with a casing, a fire-pot, having a series of openings which communicate with an exit-space formed intermediate the fire-pot and casing, a perforated air-heating chamber forming a part of the fire-pot structure, a water-jacket located in said exit-space and above the air-heating chamber, an exit-flue communicating with the space above the water-jacket, and means for introducing currents of air toward the fuel, said air-currents being drawn through the fuel under the influence of the draft.

25. In a downdraft-stove, the combination with a casing, a fire-pot, having a series of openings at the bottom which communicate with a space intermediate the fire-pot and casing, an air-heating chamber having air-exits in the fire-pot, said chamber being adjacent the fire-pot, means for introducing air to said chamber, means for introducing individual currents of heated air above the fuel, all of said currents being drawn through the fuel under the influence of the draft, substantially as described.

26. In a downdraft-stove, the combination with a casing, a fire-pot, an exit-flue, an air-heating chamber adjacent the fire-pot, said chamber having a series of air-exits, means for introducing air to said chamber, means for introducing air in individual currents to the body of the fuel, means for delivering heated air-currents to the fuel at different levels, all of the air-currents being drawn through the fuel under the influence of the draft, and a plurality of air-pockets in the fire-pot, substantially as described.

27. In a downdraft-stove, the combination with a fire-pot having openings at its lower and which communicate with a space formed intermediate the casing and fire-pot, an exit-flue, an air-heating chamber adjacent the fire-pot, means for supplying air to the chamber, a series of exit-openings being formed in the chamber at different angles and of different sizes to deliver air-currents at varying angles and proportions, said air-currents being drawn through the fuel under the influence of the draft, substantially as described.

28. In a downdraft-stove, the combination with a casing, a fire-pot having grooves therein and being provided with openings which communicate with a space formed intermediate the casing and fire-pot, a plurality of air-pockets above the grooves which communicate therewith, an exit-flue and means for introducing air above the fuel, said air being drawn through the fuel under the influence of the draft, substantially as described.

698,811. LOCK, HENRY G. CARLSON, New York, N. Y., assignor to Carleton Electric Company, New York, N. Y., a Corporation of New York. Filed March 14, 1901. Serial No. 61,988. (No model.)

Claim.—The combination with an electrical lock of an electromagnet having one terminal electrically connected to an insulated point in the face-plate, the second terminal of said magnet being electrically connected to the lock-case and face-plate; a movable electrical contact on the strike-plate, registering with said insulated contact, to complete one side of the circuit, and two or more movable contacts in the lock-case, electrically connected in parallel or multiple to engage the strike-plate and complete the second side of said circuit with a metal guide-plate upon the outside of the opening, to prevent interference with said contacts.

698,812. LOCK, HENRY G. CARLSON, New York, N. Y., Filed Apr. 17, 1901. Serial No. 62,182. (No model.)

Claim.—1. In a lock, the combination with the movable engaging part, of a locking member therefor, consisting of a three-armed lever, supported on a pivot, and a separate actuating device for each arm of said lever.

2. In a lock, the combination with the movable engaging part, of a locking member therefor, consisting of a pivotally-supported lever having three arms, one forming an armature for an electromagnet, the second forming an engaging-point for a key-operated cam and the third forming an engaging-point for a knob-operated cam; an electromagnet, a key-operated device and a knob-operated cam for actuating said lever.

3. In a lock, the combination with the movable engaging part, of a locking member therefor, means for shifting said locking member consisting of two oppositely-rotatable cams, a spindle-cam or opening in each cam to receive a spindle entering from opposite directions, respectively, opening-inlets and a wall or partition separating the openings or spindle-cams.

4. In a lock, the combination with the movable engaging part, of a locking member therefor, consisting of a multiple-armed lever, a knob-edge support therefor, and a transverse engaging with the casing of the lock.

5. In a lock, the combination with the movable engaging part, of a locking member therefor, consisting of a multiple-armed lever, a knob-edge bearing or support therefor with a pair of lugs and a pair of transverse lugs at right angles to each other to prevent displacement.

6. In a lock, the combination with the movable engaging part, of a locking member therefor, consisting of a lever having a plurality of arms or engaging-points and a knob-edge support or bearing for said lever fixed upon the lock-casing.

698,818. MANTON ALARM AND PATENTING DEVICE. HENRY G. CARLSON, New York, N. Y., Filed Apr. 23, 1901. Serial No. 67,665. (No model.)

Claim.—The combination of a sliding frame, a casing for said frame, a lever in said casing pivoted at one end, an auto-angled hook on the opposite end, a catch for said hook fixed on said frame, a cam-like projection on said lever between said pivot and hook, in the path of said catch, a drum-cam operated by said lever, an electrical circuit and an indicator in said circuit.

698,814. DOUGH-MANIPULATING AND SHAPE-FORMING MACHINE. HENRY G. CARLSON and EDWARD E. HENRY, San Francisco, Cal., Filed July 2, 1901. Serial No. 67,976. (No model.)

Claim.—1. An apparatus for forming leaves of bread from dough, consisting of means for folding the edges of a sheet of dough upon the main portion, means for compressing the folded portion and cutting them with the main sheet, means for folding the front edge of the sheet upon

back, means for compressing the fold thus made upon the main portion, means for covering the sheet to the proper length, means for again folding the dough upon itself, and means for compressing the fold thus made, and means for producing a final fold and compression to form the loaf.

2. An apparatus for forming bread from dough consisting of rolls between which the dough is reduced to a sheet, an endless traveling belt and a guide intermediate between it and the rolls whereby the dough is transferred upon said belt, rolls journaled upon each side of the belt and revolvable laterally so as to fold the edges of the sheet of dough over upon the main portion, and rolls between which the folded sheet is passed whereby it is compressed.

3. In an apparatus for the manufacture of loaves from dough, means for reducing the dough to a flat sheet, an endless traveling belt upon which said sheet is delivered, rolls journaled parallel with and overlapping the edges of the sheet, and revolvable laterally, said rolls being actuated and rotating in diameter from the receiving to the discharge and whereby the edges of the sheet of dough are folded over upon the main body.

4. In an apparatus for the manufacture of loaves from dough, means for reducing the dough to a flat sheet, means for folding the edges of said sheet upon the central portion, means for again reducing the folded parts to a flat sheet, an endless traveling belt upon which said sheet is delivered, a reciprocating plate against which the end of the moving sheet contacts, and by which it is folded backwardly upon the main portion, and a vertically-movable plate by which said fold is pressed down upon the main portion.

5. In an apparatus for the manufacture of loaves from dough, means for reducing the dough to a flat sheet, and means for folding the edges of said sheet and pressing them upon the main body, a horizontal endless traveling belt upon which the sheet of dough is delivered, vertical endless traveling belts disposed upon each side of the main belt between which the edges of the sheet are carried, and vertically-reciprocating plates located above the horizontal belt whereby the sheet is folded and the fold is successively compressed together.

6. In an apparatus for the manufacture of loaves from dough, mechanism by which a sheet is formed from the dough, mechanism by which the edges are folded laterally and compressed upon the main portion, a horizontally-moving endless belt and vertical side belts between which the sheet of dough passes, a vertically-reciprocating folding plate located above the horizontal belt, said plate carrying an extension by which the fold is compressed upon the main portion, and a cutter by which the sheet is cut into regular lengths.

7. In an apparatus for forming loaves from dough, mechanism by which the dough is formed into a continuous sheet of equal width and thickness, an endless traveling horizontal belt and vertical side belts by which the sheet is guided, a reciprocating folding and compressing plate

and cutter for covering the sheet into lengths, and a cam by which said plate is actuated in unison with the movements of the belt.

8. In an apparatus for the manufacture of leaves from dough, mechanism by which the dough is reduced to a continuous sheet of equal width and thickness, an endless traveling belt upon which the sheet is delivered, side guiding-belts acting in unison therewith, a reciprocating folding, compressing and cutting plate, a lever-arm upon which it is carried and a cam by which it is actuated, and supplemental folding and compressing plates with actuating-cams, said cams and plates being operated in unison with each other and the movements of the belt.

9. In an apparatus for the manufacture of leaves from dough, mechanism by which the dough is formed into an endless sheet of equal width and thickness, an endless traveling belt upon which the sheet is delivered and guides upon the sides thereof, means for folding the sheet, compressing the folds and cutting the sheet into approximately equal lengths, and means for discharging the finished leaves from the end of the traveling belt.

10. In an apparatus for the manufacture of leaves from dough, mechanism by which the dough is formed into a continuous sheet of equal width and thickness, an endless traveling horizontal belt upon which the sheet is delivered, means movable in relation to said belt whereby the sheet is folded upon itself and the folds compressed to form a leaf, vertically-disposed endless belts traveling upon each side of the main carrying-belt to act as guides, means for separating said guide-belts at the end of their travel whereby the leaves are released from and pass over and allowed to be discharged.

11. In an apparatus for the manufacture of leaves from dough, mechanism by which the dough is formed into a continuous sheet of equal width and thickness, mechanism by which it is folded, the folds compressed to form a leaf, and the dough covered into lengths of approximately equal size, a discharge over which the finished leaves are delivered and slideable receiving trays or boards, with means for moving them so that the leaves are received successively upon the boards.

12. In an apparatus for the manufacture of leaves from dough, mechanism by which the leaves are formed and delivered from the apparatus, receiving trays or boards, supporting-rollers and an endless traveling chain with lugs by which the trays are moved, guides by which their line of travel is maintained, cloth-rolls mounted upon the front of each board, and means by which the cloth is unrolled as the boards advance to form a surface for the reception of the leaves.

13. In an apparatus for the manufacture of leaves from dough, mechanism by which the leaves are formed from the sheet and delivered from the end of the apparatus, receiving trays or boards with means for moving them in the line of delivery, cloth-rolls attached to the front of each board, standards upon each side having channels into which the shafts of the cloth-rolls are carried by the movement of the board whereby the cloth is unrolled to form a surface for the reception of the leaves.

14. In an apparatus for the manufacture of leaves from dough, boards or trays upon which the finished leaves are delivered, means by which said boards are caused to advance in unison with the delivery, cloth-rolls having the ends attached to the front of the board, elastic standards located upon each side having bearings into which the shafts of the cloth-rolls are carried, and within which they revolve during the passage of the board, and lugs upon each side of the rear of the board whereby the standards are operated, and the shaft of the unrolled roll allowed to pass out with the board.

15. In an apparatus for the manufacture of leaves from dough, mechanism by which the leaves are formed, movable trays or boards upon which the leaves are delivered, cloth-rolls connected with each of the boards to form a surface for the reception of the leaves, and a mechanism by which the cloth is raised into folds between the contiguous leaves.

16. In an apparatus for the manufacture of leaves from dough, trays or boards and mechanism by which they are moved in the line of delivery of the finished leaves, said trays having cloth-rolls connected therewith, and means for unrolling the cloth to form a surface for the reception of the leaves, clamps upon each side of the boards and mechanism by which they are caused to raise the edges of the cloth and mechanism by which they are advanced more rapidly than the movement of the trays whereby the cloth is lifted into folds after the deposit of each leaf and between it and the next.

17. In an apparatus for the manufacture of leaves from dough, boards or trays upon which the completed leaves are delivered, cloth-rolls connected with the boards to provide a surface for the reception of the leaves, a shaft journaled beneath the trays, having arms upon its ends, spring-pressed lever-clamps carried by said arms and means for advancing said clamps so as to grip the edges of the cloth at each revolution of the shaft whereby the cloth is lifted into folds between one leaf and the succeeding one, and means for disengaging the clamps after the fold has been formed to allow the shaft to continue its revolution.

698,815. CARPET-RAG LOOPER. THOMAS A. CLARK, LANSING, MICH. Filed Mar. 22, 1901. Serial No. 88,664. (No model.)

Claim.—A carpet-rag looper comprising a base, a blade carried thereby formed with a pointed upper end and slotted below said point, and a U-shaped support secured to the base having the legs thereof extending at each edge of the blade and formed with convolutions, and having its doubled end extending beyond the free end of the blade, substantially as described.

698,816. SCREEN. WILLIAM E. CONRAD, JR., DELPHI, OHIO, ASSIGNOR OF TWO-THIRDS TO JOHN A. BROWN, DEANDER, IND. Filed June 17, 1901. Serial No. 84,918. (No model.)

Claim.—1. A screen comprising a wire-netting and sheet-metal strips bent longitudinally to clamp the side edges and the top and bottom thereof, the top and bottom strips being again bent and inclosing the ends of the side strips.

2. A screen comprising wire-netting, a sheet-metal frame, each member of which is bent to clamp an edge of the wire-netting and a lift or pull having a part inserted between the folds of a member of the frame and clamped in place thereby.

3. In a window-screen, the combination with two members, each comprising a sheet-metal frame clamped to the edges of the wire-netting, of guides clamped with the netting to the top and bottom strips of one of said members and embracing the top and bottom strips of the other member and a lift clamped to the bottom strip of each member.

698,817. GLASS-BLOWING MACHINE. EMERY J. CULBERT, Toledo, Ohio. Filed Apr. 12, 1904. Serial No. 677,412. (No model.)

Claim.—1. In a glass-blowing machine, a sectional mold and a movable support therefor, a support for a detachable blowpipe, means for intermittently moving the mold and blowpipe supports, and means for blowing the article while the mold and blowpipe supports are stationary.

2. In a glass-blowing machine, comprising a mold, and a traveling support for the blowpipe, means at a point in the travel of said support where it is held, stationary, a connection at that point for supplying the blowpipe with air under pressure for blowing, and means for moving the blowpipe away from the blowing connection.

3. In a glass-blowing machine, a traveling frame having a support for the blowpipe, a mold and a source of air-supply for the blowpipe, a motor for operating said frame which is stopped at the blowpipe-support reaches the blowing-point and mechanism under the control of the operator for starting the travel of the machine after each stoppage.

4. In a glass-blowing machine, a traveling frame having a mold, a support for the blowpipe and an air-supply connection therefor, a motor for intermittently moving the frame, and stopping it with the mold at the blowing-point, mechanism under the control of the operator for starting said frame after each stoppage and means at the stopping-point for closing the mold.

5. In a glass-blowing machine, an intermittently-traveling frame

carrying the blowpipe and the mold, means under the control of the operator for closing the mold and effecting the blowing while the frame remains at its stopping-point and for causing the frame to move a predetermined distance and to stop.

6. In a glass-blowing machine, the combination with the mold, of a lever joining the mold, a tank, and means for rotating the lever and rocking it upon its fulcrum, to lower the mold into and raise it out of the tank, and to move it to and from the point at which the blowpipe is inserted.

7. In a glass-blowing machine, a pair of molds, a tank vertical guide upon which the molds move, a lever to the ends of which the molds are connected, and means for rocking the lever and rotating it to move the molds around its fulcrum and raise and lower them in relation to the tank.

8. In a glass-blowing machine, an air chamber or duct connecting with the article to be blown, means for blowing the article by reducing the size of the connecting chamber or duct and means for automatically determining and maintaining the maximum pressure to which the air is compressed.

9. In a glass-blowing machine, the combination of a movable support for the blowpipe, means for rotating the blowpipe and means for causing the blowpipe-support to travel, of a single actuating device adapted to be connected alternately with the blowpipe-rotating device and the device for moving the blowpipe-support.

10. In a glass-blowing machine, the combination of the blowpipe-support, the blowpipe-actuating device for rotating the blowpipe and a motor adapted to be connected with said actuating means after the blowpipe is in its support under the control of the operator.

11. In a glass-blowing machine, the combination of the upright shaft B carrying the blowpipe-supporting arm, a blowpipe-coupler carried thereon, a motor for rotating the blowpipe-coupler, and means under the control of the operator for connecting the motor with said coupler to rotate the same.

12. In a glass-blowing machine, the combination of the vertical standard B carrying the blowpipe-support, a coupler for the blowpipe connecting it with the source of air-supply through a duct carried by said shaft, a gear connection for rotating the coupler, a gear connection for rotating the shaft and a drive-gear adapted to be alternately connected with the blowpipe-actuating device and the drive mechanism for the shaft.

13. In a glass-blowing machine, the combination with the mold the blowpipe, a support for the blowpipe, the air-supply device for the blowpipe, means for producing a relative rotation between the article and the mold, and means under the control of the operator for setting into operation the rotating device and for automatically stopping the same at the end of a predetermined time.

14. In a glass-blowing machine, the combination of the mold, the blowpipe-support, means for effecting a relative rotation movement between the article in its blown and the mold, a motor and means under the control of the operator for setting it in operation which after the mold is closed will supply air for the blowing and effect the rotation mentioned for a predetermined time.

15. In a glass-blowing machine, the combination of the sectional mold, a support for the blowpipe at the point where the mold remains stationary, means for supplying air under pressure at said point, a motor to cause the mold to travel intermittently to open the same and a motor, under the control of the operator for effecting the blowing and after the blowing to cause the mold to travel away from the blowing-point to open the mold and wet the same.

16. In a glass-blowing machine, the combination of the traveling coupler B, means for automatically lifting the coupler at the blowing-point, means under the control of the operator for effecting the coupling with the blowpipe.

17. In a glass-blowing machine, the combination of the vertically-reciprocating coupler for connecting the air-supply pipe to the blowpipe and means for raising and lowering said coupler, consisting of the inclined head 14 upon which the coupler is adapted to be lifted and supported, and means for withdrawing said support beneath the coupler, substantially as described.

698,818. GLASS-BLOWING MACHINE. LEMUEL H. CULBERT, Toledo, Ohio, assignor to the Toledo Glass Co., Toledo, Ohio, a Corporation of Ohio. Filed Apr. 28, 1904. Serial No. 678,722. (No model.)

Claim.—1. In a glass-blowing machine, a sectional mold, opening in a horizontal plane, a movable cam for opening and closing the mold in each operation and for positively holding it open at the close of the operation, means under the control of an operator for starting the cam, and automatic means for stopping it.

2. In a glass-blowing machine, in which there are employed a mold and a detachable blowpipe, sprinkling device for the mold comprising a storage-reservoir, means for supplying water thereto started by the location of the blowpipe in its support and means for stopping the supply upon the withdrawal of the blowpipe.

3. In a glass-blowing machine, the combination of a blowpipe supported in operative relation to the mold, of an air-supply for delivering air under pressure to the article to be blown arranged in proximity to the mouth of the blowpipe, and means for varying the pressure of air in the article to be blown after each operation by varying the distance of said air-supply from the blowpipe during the blowing period.

4. In a glass-blowing machine, comprising the blowpipe supported in operative relation to the mold, of a nozzle arranged in proximity to the blowpipe and connected with a source of air-supply and automatic means for raising and lowering said nozzle to change its proximity to the blowpipe during each blowing period.

5. In a glass-blowing machine comprising a mold and a blowpipe supported in operative relation thereto, a source of air-supply under pressure having its discharge adjustably supported in proximity to the mouth of the blowpipe, of automatic mechanism for varying the distance between said air-supplying means and the blowpipe during the blowing period to change the pressure in the article to be blown.

6. In a glass-blowing machine the combination with a sectional mold, a support for the blowpipe and a sliding air-supply nozzle arranged in line, a vertical shaft extending in the machine beside said parts, a drive connection at the bottom from said shaft to the mold and at the top from said shaft to the air-supply nozzle, and an intermediate drive connection from said shaft to the blowpipe-support, with means for rotating said blowpipe in its support.

698,819. RUBBER-ROLLING. WILLIAM CONNELLEY, Toledo, Ohio. Filed May 6, 1904. Serial No. 68,911. (No model.)

Claim.—1. In a rod-coupling, the combination of a tubular sleeve of uniform bore, having an exterior reduced portion at one end forming an end shoulder for engaging an elevator, and a longitudinal slot extending from end to end along one side, cutting through the wall of the sleeve, and provided with a plurality of pairs of ears integral with the sleeve projecting laterally at intervals along the sleeve, the ears of each pair being on opposite sides of the slot, a compression-bolt through each pair of ears, and a stop within the orifice of the sleeve, projecting from one side of the interior wall, adapted to limit the distance that a rod may be introduced into the sleeve from each end respectively.

2. In a rod-coupling, the combination of a tubular sleeve, having a central and an end reduced portion forming shoulders for engaging an elevator, and a longitudinal slot extending from end to end of the sleeve and through the wall of the sleeve along one side, and provided with a plurality of pairs of ears integral with the sleeve, on each side of the central reduced portion, projecting laterally at intervals along the slot, the ears of each pair being on opposite sides of the slot, a compression-bolt through each pair of ears; a stop projecting radially within the orifice of the sleeve, adapted to limit the distance that a rod may be introduced into the sleeve from each end respectively.

3. In a rod-coupling, the combination of a tubular sleeve, having a central and an end reduced portion forming shoulders for engaging an elevator, and a longitudinal slot extending from end to end of the sleeve and through the wall of the sleeve along one side, and provided with a plurality of pairs of ears integral with the sleeve, on each side of the central reduced portion, projecting laterally at intervals along the slot, the ears of each pair being on opposite sides of the slot; a compression-bolt through each pair of ears; a stop projecting radially within the orifice of the sleeve, adapted to limit the distance that a rod may be introduced into the sleeve from each end respectively; and an annular groove in the inner wall of the sleeve, adjacent to the abutting face of each stop.

698,820. **THOMAS PUGH.** **ROBERT GERRARD, ROBERT, H. J.** assignor to J. A. Sayre & Co., Newark, N. J., a firm. Filed Feb. 28, 1901. Serial No. 66,646.

Claim.—A combination punch-punch; comprising a punch-carrying member, with its pivoted and bifurcated; having formed upon one branch thereof a sheet-edge-perforating punch; and upon the other branch a sheet-edge-perforating punch; and a die-carrying member, having two dies and slots, adapted to correspond with the radius of and to articulate with the two punches of the punch-carrying member, substantially as shown and described, and for the purpose set forth.

698,821. **WILLIAM F. HUBBARD FOR LOOMER.** **ARTHUR S. OWAN** and **BENJAMIN F. HUBBARD, Worcester, Mass.** assignors to **Shawmut & Knapp Loom Works, Worcester, Mass.** a Corporation of Massachusetts. Filed Nov. 7, 1901. Serial No. 51,460. (No model.)

Claim.—1. In a loom of the class described, a box-pattern chain-cylinder, and two multiplier-pattern chain-cylinders, all on the same shaft, mechanism for operating the box-pattern chain-cylinder, and the multiplier-pattern chain-cylinder, and mechanism, intermediate the box-pattern chain-cylinder and the multiplier-pattern chain-cylinder, substantially as shown and described.

2. In a loom of the class described, a box-pattern chain-cylinder, and two multiplier-pattern chain-cylinders, all on the same shaft, mechanism for operating the box-pattern chain-cylinder, and the multiplier-pattern chain-cylinder, and mechanism, intermediate the box-pattern chain-cylinder and a sliding bar, which engages with the hubs of the multiplier-pattern chain-cylinders, substantially as shown and described.

3. In a loom of the class described, the combination with the box-pattern chain-cylinder, of two multiplier-pattern chain-cylinders on the same shaft with the box-pattern chain-cylinder, substantially as shown and described.

4. In a loom of the class described, the combination with the box-

pattern chain-cylinder, of two multiplier-pattern chain-cylinders on the same shaft with the box-pattern chain-cylinder, and mechanism intermediate the box-pattern chain-cylinder and the two multiplier-pattern chain-cylinders, substantially as shown and described.

5. In a loom of the class described, the box-pattern chain-cylinder, and two multiplier-pattern chain-cylinders on the same shaft with the box-pattern chain-cylinder, mechanism intermediate the two multiplier-pattern chain-cylinders and the box-pattern chain-cylinder, a pattern-carrier on the box-pattern chain-cylinder, having three different diameters of pattern-carriers, an indicator-lever for said different-diameter surfaces, and connections, intermediate said lever and the multiplier-pattern chain-cylinder, to control the operation of said cylinder, substantially as shown and described.

698,822. **CONVEYER.** **GEORGE W. CHAM, Germantown, Pa.** Filed Sept. 9, 1901. Serial No. 74,712. (No model.)

Claim.—1. In a conveyor, the combination with a chain, of a U-shaped flight extending therewith, the side members of said flight lying substantially parallel with said chain, substantially as described.

2. In a conveyor, the combination with a chain, of U-shaped flights extending therewith, the members of said flight lying substantially parallel with said chain, the outer edges of said flights conforming generally to the shape of said chain, substantially as described.

3. In a conveyor, the combination with a chain having inclined sides, of U-shaped flights extending with said chain and curved by chains, the members of said flight lying substantially parallel with said chain, substantially as described.

4. In a conveyor, the combination with a chain, of chains, and a flight comprising a main operative portion at right angles to said chain and sides arranged in a plane substantially parallel with said chain and connected with said chain, substantially as described.

5. In a conveyor, the combination with a chain, of chains and a flight comprising a main operative portion at right angles to said chain and sides lying substantially parallel with the plane of said chain and secured to said chain, the outer edges of said flights conforming generally to the shape of said chain, substantially as described.

6. In a conveyor, the combination with a chain, of chains and a flight comprising a main operative portion at right angles to said chain and sides lying substantially parallel with the plane of said chain and secured to said chain, the outer edges of said flights conforming generally to the shape of said chain, substantially as described.

7. In a conveyor, the combination with a chain, of chains and a flight comprising a main operative portion at right angles to said chain, sides curved to said chain and outwardly-projecting ends, substantially as described.

8. In a conveyor, the combination with a chain having inclined sides, of chains and a flight comprising a main operative portion at right angles to said chain, sides curved to said chain and outwardly-projecting ends, having beveled under edges with the hub of the sides of said chain, substantially as described.

9. An integral U-shaped conveyor-flight having a main operative portion and sides at an angle thereto, and means for securing said sides to driving-chains so as to dispose said flight in a plane substantially parallel with the plane of the chain passing therewith, substantially as described.

10. An integral U-shaped conveyor-flight and means for securing the sides thereof directly to driving-chains, so as to dispose said flight in a plane substantially parallel with the plane of the chain passing therewith, substantially as described.

11. A conveyor-flight comprising a main operative portion, sides substantially at right angles thereto and outwardly-projecting ends, substantially as described.

12. A conveyor-flight comprising a main operative portion, sides substantially at right angles thereto and outwardly-projecting ends, substantially parallel with said main portion, as set forth.

13. A conveyor-flight comprising a main operative portion, sides substantially at right angles thereto and outwardly-projecting ends, having beveled under edges, substantially as described.

14. A conveyor-flight comprising a main operative portion, sides substantially at right angles thereto and outwardly-projecting ends, substantially parallel with said main portion, and having beveled under edges, substantially as described.

15. An integral conveyor-flight comprising a main operative portion, sides substantially at right angles thereto, means for attaching said sides to driving-chains and outwardly-projecting ends, substantially parallel with said main portion, as set forth.

698,828. **THEY-BROOKER.** **JOHN W. BULLMAN, Chicago, Ill.** assignor to International Time Recording Company, Washington, D. C., a Corporation of New Jersey. Filed Oct. 10, 1901. Serial No. 70,804. (No model.)

Claim.—1. In combination, a manually-adjustable printing-form automatically operated by a clock-movement and recording mechanism adapted to be operated manually for taking impressions from said printing-form, and means for compelling a properly-correlated operation of said mechanism comprising a manually-reversible automatic shutter mechanism adapted to render the recording mechanism functionally inoperative at the end of a predetermined interval and a clock-operated controller arranged to control the manual restoration of said shutter mechanism.

2. In combination, mechanism operated automatically by a clock-movement and mechanism operable manually and means for compelling a properly-correlated operation of said mechanism comprising manually-reversible means operating automatically to render the manually-operable mechanism functionally inoperative at the end of a predetermined interval and a clock-controlled synchronous automatic disabling mechanism.

3. In combination, mechanism operated automatically by a clock-movement and mechanism operable manually and means for compelling a properly-correlated operation of said mechanism comprising manually-reversible means operating automatically to render the manually-operable mechanism functionally inoperative at the end of a predetermined interval and a clock-controlled synchronous disabling mechanism.

4. In a time-recorder, the combination of a clock-actuated printing-form, a card-carrier, means for moving the printing-form manually relatively to the card-carrier, a shutter mechanism automatically operating to prevent registration at the end of a given interval of time, and inter-connections between said shutter mechanism and manually-reversible printing-form, whereby the adjustment of the printing-form to the proper printing position effects the opening of the shutter mechanism.

5. In a time-recorder or analogous machine, a mechanism for controlling a shutter or the like, comprising a clock-actuated rotary element having a stepped outer rim of shoulders, a pawl mounted upon a carrier adapted to be advanced step by step and adapted to engage the shoulders of said rotary element to shift the latter, and operative connections between the rotary element and the shutter whereby the shifting of the former operates the shutter.

6. In a time-recorder or analogous machine, means for controlling registration upon said machine comprising a shutter mechanism, a clock mechanism automatically operating said shutter mechanism, a co-operating mechanism adapted to be actuated manually and operative connections between said co-operating mechanism and said shutter mechanism, whereby the actuating of the former operates the latter.

7. In a time-recorder or the like, the combination of a shutter mechanism, a clock mechanism actuating said shutter mechanism automatically, a clock-actuated element for controlling one of the operations of said shutter, a synchronizing mechanism whereby said controlling element is moved by the clock mechanism and means for opening said shutter mechanism manually through the medium of said controller.

8. In a time-recorder or the like, a clock mechanism, a shutter mechanism operated to close automatically at the end of a predetermined interval, a shutter-controlling element, a synchronizing mechanism whereby said controlling element is moved regularly with the clock-movement, a manually-operable member arranged to act upon said shutter-controlling element to operate the shutter mechanism through said controlling element, said shutter-controlling element being arranged to receive relatively from the manually-operable element regularly in proportion to the period of time elapsed between operations, and a co-operating instrumentally connected with and adapted to be actuated by the advance of the manually-operated element.

9. In a time-recorder or the like, a clock mechanism, a shutter mechanism operated to close automatically at the end of a predetermined interval, a rotary shutter-controlling element, a synchronizing mechanism whereby said controlling element is rotated regularly with the clock-movement, a manually-operable member arranged to act upon the shutter-controlling element to operate the shutter mechanism through said controlling element, said shutter-controlling element being provided with a spirally-arranged part adapted for engagement by the manually-operable element, and extending outwardly around said element, whereby the regular rotation of said element causes said spirally-arranged part to receive from the manually-operable element continuously and a complete revolution to thrust and repeat this operation during each cycle of movement of said rotary element.

10. In a time-recorder or the like, a clock mechanism, a shutter mechanism operated to close automatically at the end of a predetermined interval, a rotary shutter-controlling element, a synchronizing mechanism whereby said controlling element is rotated regularly with the clock-

movement, a manually-operable member arranged to act upon the shutter-controlling element to operate the shutter mechanism through said shutter-controlling element, said shutter-controlling element being provided with a spirally-arranged part adapted for engagement by the manually-operable element, and extending entirely around said element, whereby the regular rotation of said element causes said spirally-arranged part to rotate from the manually-operable element continuously until a complete revolution is formed and repeats this operation during each cycle of movement of said rotary element, and a reciprocating mechanism operatively connected with said manually-operable element and adapted to be actuated by the manual operation of the latter to operate the shutter.

11. In a time-recorder or analogous machine, means for controlling registrations upon said machine, comprising a shutter mechanism, a clock mechanism arranged to operate said shutter mechanism automatically, a rotary shutter-controlling element having a cylindrical portion provided with a spirally-arranged series of shoulders controlling said cylindrical portion, a synchronizing mechanism whereby said shutter-controlling element is stepped forward regularly with the clock-movement, a manually-operable pawl arranged to traverse said shutter-controlling element in a direction transversely to its direction of rotary movement, means for stepping forward said pawl step by step, a printing-form movably mounted upon ways and operative connections between said manually-operable pawl and said printing-form whereby the printing-form is moved synchronously with the movement of the pawl and to a corresponding extent.

12. In a time-recorder or analogous machine, means for controlling registrations upon said machine, comprising a shutter mechanism, a clock mechanism arranged to operate said shutter mechanism automatically, a rotary shutter-controlling element having a cylindrical portion provided with a spirally-arranged series of shoulders controlling said cylindrical portion, a synchronizing mechanism whereby said shutter-controlling element is stepped forward regularly with the clock-movement, a manually-operable pawl arranged to traverse said shutter-controlling element in a direction transversely to its direction of rotary movement, means for stepping forward said pawl step by step, a printing-form movably mounted upon ways and operative connections between said manually-operable pawl and said printing-form whereby the printing-form is moved synchronously with the movement of the pawl and to a corresponding extent, and a step arranged to positively limit the advance movement of the pawl beyond that step which affects the operation of the shutter.

13. In a time-recorder, or like, a clock mechanism, a shutter mechanism, operated to close automatically at the end of a predetermined interval, a rotary shutter-controlling element, synchronizing mechanism whereby said shutter-controlling element is rotated regularly with the clock-movement, a manually-operable member arranged to act upon the shutter-controlling element to open the shutter mechanism through movement imparted to said shutter-controlling element, said shutter-controlling element being provided with a spirally-arranged part adapted for engagement by the manually-operable element, so disposed relatively to the direction of movement of said manually-operable element as to rotate therefrom during the rotation of the shutter-controlling element, a printing-form movably mounted upon ways, operative connections between said printing-form and said manually-operable element whereby the printing-form is moved with the manually-operable element, and a ratchet mechanism arranged to control the operation of said manually-operable element, said ratchet mechanism being arranged to prevent return movement of the manually-operable element until a complete cycle of movement has been performed.

14. In a time-recorder or the like, a clock mechanism operated to close automatically at the end of a predetermined interval, a rotary shutter-controlling element, synchronizing mechanism whereby said shutter-controlling element is rotated regularly with the clock-movement, a manually-operable element, and a ratchet mechanism arranged to control the operation of said manually-operable element, comprising a notched segment, a reversible pawl arranged to act upon said segment, and a reversing mechanism arranged to reverse said pawl at the end of the throw of the segment in each direction.

15. In a time-recorder, the combination of a clock mechanism; a shutter mechanism operated by said clock mechanism to close automatically at the end of a predetermined interval, a rotary shutter-controlling element provided with a cylindrical portion controlled by a series of shoulders arranged spirally thereon, said shutter-controlling element being mounted to reciprocate endwise or in the direction of its axis of rotation, a ratchet-bar arranged to reciprocate parallel therewith, and a pawl carried by said ratchet-bar and adapted to engage said shutter-controlling element, a crank-shaft provided with a gear operatively engaging said ratchet-bar, a printing-form movably mounted upon ways and carrying a rack, gear connection between said shaft and the rack of said printing-form, a shiftable member operatively connected with said shutter mechanism and adapted to be engaged by the advance movement of the shutter-controlling element and adapted to open the shutter, synchronizing mechanism connecting said

shutter element and said clock-movement whereby said element is rotated regularly and synchronizing mechanism connecting said printing-form with said clock-movement.

16. In a time-recorder, the combination with the main frame of a clock-movement, a printing-form carriage mounted to reciprocate upon ways upon said main frame, a set of printing-forms mounted upon said carriage, driving connections between said clock-movement and printing-forms, and a card-receiver mounted to reciprocate in a direction transversely to the direction of movement of the printing-form carriage upon its ways, said printing-form carriage being provided with laterally-disposed upstanding arms, the upper ends of which extend at opposite sides of the card-receiver, a balance-shaft supported upon said arms above the card-receiver and a printing-hammer operatively mounted upon said shaft, substantially as described.

17. In a time-recorder, the combination with the printing-forms, of a throat or recording-passages arranged to extend adjacent to said printing-forms and means for controlling the insertion of the recording instrument comprising a shutter-bar pivotally mounted between its ends and having one end arranged to oscillate across said throat, a shutter-actuating bar mounted to reciprocate in a direction transversely to the shutter-bar, provided with an inclined cam-disk operatively connected with the latter, an inclined cam projection upon said shutter-actuating bar and a clock-actuated plunger arranged to act upon said inclined cam projection to shift the bar as the plunger is reciprocated and a small-cam connected with the clock-movement and operating to reciprocate the plunger at regular intervals.

18. In a time-recorder, the combination with the printing-forms, of a throat or recording-passages arranged to extend adjacent to said printing-forms and means for controlling the insertion of the recording instrument comprising a shutter-bar pivotally mounted between its ends and having one end arranged to oscillate across said throat, a shutter-actuating bar mounted to reciprocate in a direction transversely to the shutter-bar, provided with an inclined cam-disk operatively connected with the latter, an inclined cam projection upon said shutter-actuating bar and a clock-actuated plunger arranged to act upon said inclined cam projection to shift the bar as the plunger is reciprocated and a small-cam connected with the clock-movement, and operating to reciprocate the plunger at regular intervals, said plunger being provided with a cam-engaging wiper pivotally connected with a cam-block forming part of the plunger and held positively against pivotal movement during the advance movement of the plunger but free to oscillate in the opposite direction during the return movement of the plunger whereby the engaging end of the wiper is caused to travel around the cam projection, substantially as described.

19. In a time-recorder, the combination with the main frame and a clock mechanism mounted thereon, of a set of printing-forms mounted to reciprocate upon ways upon said main frame, driving connections between said printing-forms and the clock-movement, manually-operable means for adjusting said printing-forms along said ways and means for controlling the adjustment of the printing-forms and recording upon the machine, comprising a rotary controller provided with a spirally-arranged surface adapted for engagement by an actuating member, operative connections between said controller and the clock-movement whereby the controller is moved regularly and proportionately to the length of time elapsed, means for manually shifting said controller bodily in the direction of its axis of rotation, a shutter-bar pivotally mounted to oscillate across the throat of the recording aperture, a shutter-actuating pawl mounted to reciprocate in a direction transversely to the shutter-bar and provided with an inclined cam with which the shutter-bar is operatively connected, a second inclined cam upon said shutter-actuating bar, a reciprocating plunger arranged to act upon said second cam, operative connections between said plunger and the clock-movement whereby the plunger is reciprocated at regular intervals to close the shutter and a lever pivoted between its ends and arranged to be actuated upon one end by the rotary controller during the bodily movement of the latter, and operatively connected with the shutter-actuating bar at its opposite end, whereby the extent of adjustment of the printing-forms upon their ways is controlled by said rotary controller and the shutter is opened automatically during the adjustment of the printing-forms and is automatically closed by the clock-movement at the end of a predetermined interval, substantially as described.

20. In combination, a tripping-dog mounted to move upon ways, and means for actuating said dog for different positions of arrangement along said ways, comprising a tripping-bar having a series of engaging shoulders arranged to extend substantially parallel with the direction of bodily movement of the dog and mounted to move bodily through an arc to approach and recede from the dog, whereby the dog is engaged during the approach of the bar and released during its retreat.

21. In combination, a pivoted tripping-dog mounted to move upon ways, and means for actuating said dog for different positions of arrangement along said ways comprising a tripping-bar provided with a series of engaging shoulders arranged to extend in a direction substantially parallel

with the direction of the bodily movement of the dog, and parallel supporting-links pivotally supporting said tripping-bar at spaced points whereby the latter is maintained in parallel relation with the ways while moved bodily through an arc to approach and recede from the dog.

22. In combination, a pivoted tripping-dog mounted to move upon ways and means for actuating said dog for different positions of arrangement along said ways comprising a tripping-bar provided with a series of engaging shoulders arranged to extend in a direction substantially parallel with the direction of the bodily movement of the dog, and parallel supporting-links pivotally supporting said tripping-bar at spaced points whereby the latter is maintained in parallel relation with the ways while moved bodily through an arc to approach and recede from the dog, and a spring arranged to act upon said bar to cause it to complete the latter part of its functional movement, whereby the tripping-bar is withdrawn from the dog promptly after it passes the "dead-center" position of the supporting-links, substantially as described.

23. In combination, a pivoted tripping-dog mounted to move upon ways and means for actuating said dog for different positions of arrangement along the ways, comprising a tripping-bar having a series of engaging shoulders extending substantially parallel with the ways, parallel links supporting said bar to cause it to move bodily through an arc while maintained parallel with the ways and means for imparting bodily movement to the tripping bar comprising an arm pivotally mounted at one end and having its intermediate portion arranged to extend between projections upon the tripping-bar, that part of the arm which works through the said projections being curved, substantially as and for the purpose set forth.

24. In combination, a pivoted tripping-dog mounted to move upon ways and means for actuating said dog for different positions of arrangement along the ways, comprising a tripping-bar having a series of engaging shoulders substantially parallel with the ways, parallel links supporting said bar to cause it to move bodily through an arc while maintained parallel with the ways and means for imparting bodily movement to the tripping-bar comprising an arm pivotally mounted at one end and having its intermediate portion arranged to extend between projections upon the tripping-bar, that part of the arm which works through the said projections being curved, a spring-pushed impression-hammer operatively engaged to move with said tripping-dog, a printing-form upon which the impression-hammer operates and a recording instrument adapted to be inserted between the printing-form and impression-hammer and having a part adapted to engage and actuate the pivoted tripping-bar-actuating arm.

25. In combination, a pivoted tripping-dog mounted to move upon ways and means for actuating said dog for different positions of arrangement along the ways, comprising a tripping-bar having a series of engaging shoulders substantially parallel with the ways, parallel links supporting said bar to cause it to move bodily through an arc while maintained parallel with the ways and means for imparting bodily movement to the tripping-bar comprising an arm pivotally mounted at one end and having its intermediate portion arranged to extend between projections upon the tripping-bar, that part of the arm which works through the said projections being curved, a spring-pushed impression-hammer operatively engaged to move with said tripping-dog, a printing-form upon which the impression-hammer operates and a recording instrument adapted to be inserted between the printing-form and impression-hammer and having a part adapted to engage and actuate the pivoted tripping-bar-actuating arm.

26. In combination with a card-holder, adapted for use in registering upon a recording-machine, a penetrating device mounted thereon, provided with a part arranged to be engaged by a relatively fixed part of the machine to force the penetrating device into a card held within said holder during a registering operation.

27. In combination with a card-holder of the character described, a penetrating device mounted thereon, provided with a part adapted to be engaged by a relatively fixed part of the machine to force the penetrating device into a card held within said holder during the recording operation and a spring acting upon said penetrating device to hold the penetrating portion thereof normally retracted.

28. In a recording-machine, the combination with the machine-frame and a card-holder adapted for insertion within a recording throat or passage in said frame, of a dog pivoted adjacent to said throat, provided at its engaging end with a plurality of teeth adapted for engagement with the card-holder and means for holding said dog yieldingly in position to project into the path of the card-holder, substantially as and for the purpose set forth.

698,824. BROOKE, CHARLES E. BROOKE, Wellington, New Zealand. Filed May 9, 1901. Serial No. 54,111. (No model.)

Claim.—1. In brush-fittings, a chamber-walled recess curved to the back of the brush and provided with an opening in the edge thereof, and a pair of arms hinged behind the recess and which are adapted to lie one on each side thereof, the front ends of which are joined together by means of a plate with pins being adapted to partially close the opening in the edge of the recess, as herein specified.

2. In brush-fittings, the combination with the back of a brush

provided with a chamber-walled recess with an opening in the edge thereof, of a pin one end of which when in closed position is curved downward toward the back of the brush and the end portion of said downwardly-curved part then curved upward into a chamber loop, said loop being fitted edgewise into said recess.

698,825. MILLER, EDWARD F. MILLER, Woodbridge, N. J. Filed Apr. 18, 1899. Serial No. 712,571. (No model.)

Claim.—1. The combination in a vertical water-tube boiler of one or more oblong sections, composed of one upper and one lower drum connected by water-tubes, and an open furnace or combustion-chamber on one or both sides of said section and extending the length of said section and an outside casing at each end of said furnace or combustion-chamber and extending over the ends of said section, and in line with the said outside casing at one end of the said section, and in line with the tubes and an including wall extending from the outside casing containing the draft-outlet at the end of the said section part of the way to the other outside casing at the other end of the said section and closing communication to the tubes that lie back of the said wall and between the draft-outlet in the outside casing at the end of the said section, except through the tubes that are located in the opposite end of the said section from the draft-outlet and between the including wall and the opposite outside casing, all substantially as shown and described and for the purpose set forth.

2. In a vertical water-tube boiler the combination of a casing and upper and lower drums, water-tubes connecting the said drums, a combustion-chamber, a smoke-outlet in the casing near the lower drum in line with the water-tubes, a second outlet of smaller diameter located near the upper drum and a wall extending from the side of the casing containing the outlet, forwardly toward the opposite side of the boiler a part of the way; said wall closing communication between the combustion-chamber and the space containing the water-tubes on the other side of said wall, except at the end of said wall.

3. In a boiler-furnace the combination of cast-iron casing J, a lining therefor comprising asbestos felt F, bricks H, the arch-section K, provided with a tongue-and-groove connection, legs K upon which said section rests, bricks G resting upon the section H and the tie-rods L.

4. The combination in a vertical water-tube boiler of one or more oblong sections composed of one drum above another connected by water-tubes, a furnace or combustion-chamber on one or both sides of said section, an outside casing extending across the ends of said furnace or combustion-chamber and across the end of said section or sections, and a draft-outlet in one of said outside casings at one end of the said section and in line with the tubes and an including wall G extending from the outside casing containing the draft-outlet part of the way to the other outside casing and closing communication to the tubes that lie back of the said wall, except at the end of said wall, and a steam-outlet P in the top of the upper drum at the draft-outlet end of the said section, all substantially as shown and described and for the purpose set forth.

5. The combination in a vertical water-tube boiler of one or more oblong sections composed of one drum above another connected by water-tubes, a furnace or combustion-chamber on one or both sides of said section, an outside casing extending across the ends of said furnace or combustion-chamber and around said section and across the end of said

sections, said outside casing being composed of sections J, special brick H, draft-exits M, N' located in said outside casing at one end of said section and in line with tubes and steam-exit P in top of upper drum at same end and an insulating wall O extending from the outside casing at the same end part of the way to the opposite end of furnace or combustion-chamber to the other outside casing, substantially as shown and described and for the purpose set forth.

6. The combination is a vertical water-tube boiler of an oblong section composed of one drum above another and connected by water-tubes, the upper drum having no other means of support except the water-tubes on which it rests, said water-tubes forming the heating-surfaces of the boiler, a furnace or combustion-chamber on one or both sides of said section, a draft-exit at one end of said section and the tubes next to the draft-exit being cut off from the heat from the furnace or combustion-chamber except through the tubes open to the furnace or combustion-chamber.

7. The combination is a vertical water-tube boiler of three or more oblong sections composed of one drum above another connected by water-tubes, the upper drum having no other means of support except the water-tubes on which it rests which form the heating-surfaces of the boiler, and furnace or combustion-chamber between the said sections, and a draft-exit at one end of each of said sections and the tubes next to the draft-exits being cut off from the heat of the furnace or combustion-chamber except through the tubes open to the furnace or combustion-chamber.

698,896. DRAFT-EQUALIZER. WILLIAM S. BERRY, Ayrville, Pa. Filed Feb. 4, 1902. Serial No. 68,092. (No model.)

Claim.—1. In a draft-equalizer, the combination of a pair of levers having toothed segments concentric with their respective fulcrums, an interposed rocker having teeth meshing with the teeth of the levers, and a suitable frame supporting the fulcrums of the levers and rocker, substantially as described.

2. In a draft-equalizer, the combination of a pair of differential levers having toothed segments concentric with their respective fulcrums, an interposed rocker having teeth meshing with the teeth of the levers, a frame supporting the fulcrums of the levers and rocker, and a coiled spring connected at one end to one of the levers and at the other end to the rocker, substantially as described.

3. In a draft-equalizer, the combination of a pair of differential levers arranged in line with each other, a frame supporting the fulcrums of the levers, said frame being provided with a series of perforations arranged parallel with said levers, means interposed between the levers for transmitting movement from one to the other, said transmitting means being supported by the frame, and a link mounted upon the fulcrum of one of the levers and adapted to be connected to the frame, or to the plow, or other machine, substantially as described.

4. In a draft-equalizer, the combination of a pair of differential levers, means interposed between them for transmitting movement from one

to the other, a suitable frame supporting the fulcrums of the levers and means for locking the levers and holding them against relative movement, substantially as described.

5. In a draft-equalizer, the combination of a pair of differential levers, a rocker interposed between them for transmitting movement from one to the other, said levers and rocker having intermeshing teeth, a frame supporting the fulcrums of the levers and rocker, said frame and rocker being provided with perforations adapted to register, and a pin adapted to be inserted in said perforations for locking the rocker and thereby holding the levers in line with each other, substantially as described.

698,897. CONTROLLER FOR ELEVATORS. FRANK E. FARRITT, St. Louis, Mo., assignor to Leo Burtch, St. Louis, Mo. Filed Sept. 8, 1901. Serial No. 74,822. (No model.)

Claim.—1. In an apparatus of the character described, the combination with a plurality of doors, of an electric circuit controlled by each individual door, said circuit being closed upon the opening of a door, a motor in said circuit, and controlling device for the elevator with which said motor cooperates; substantially as described.

2. In an apparatus of the character indicated, the combination with an elevator-car, power mechanism thereby having a controller, and a door, of an electric circuit controlled by said door, a motor in said circuit, and means whereby said motor controls said controller; substantially as described.

3. In an apparatus of the character described, the combination with controlling mechanism for the car, of a motor normally out of operative connection with said controlling mechanism, and device for effectively engaging said motor with said controlling mechanism for reversing the same; substantially as described.

4. The combination with controlling mechanism of an elevator-car, of a motor for driving said mechanism to bring the car to a condition of rest, and means for disengaging said motor from said mechanism when the car is brought to rest; substantially as described.

5. The combination with controlling device of an elevator-car, of a motor, device for causing said motor to reversely drive said controlling mechanism, and a switch in the motor-circuit which is operated by the elevator-door; substantially as described.

6. The combination with controlling mechanism which is in line and operable when the car is at a landing and the door open, of means for reversing said mechanism should the actuating device be thrown to start the car away from the floor before the door is closed; substantially as described.

7. In an apparatus of the character described, a car-controlling mechanism thereby, a manually-operable device for actuating said controlling mechanism, a motor independent of the car-moving mechanism, and means for engaging the motor with the controlling mechanism when the car moves away from a landing and the door is open; substantially as described.

8. The combination with a car and its controlling mechanism, of a door, an electric circuit controlled by said door, a motor designed to cooperate with said controlling mechanism and reverse the same when the car leaves a landing and the door is open, and means for engaging the motor with said controlling mechanism; substantially as described.

9. The combination with the controlling mechanism of an elevator-car, of a motor for driving the same, a pole-changer in the motor-circuit, and means for throwing said pole-changer into pole-changing position whenever the car changes its direction of travel; substantially as described.

10. The combination with the controlling mechanism of an elevator-car, of a motor for driving the same, a door-switch in the motor-circuit, and a switch for completing the circuit whenever the actuating device of the controlling mechanism are moved to their full limit; substantially as described.

11. The combination with an elevator-car, power mechanism thereby, and a door, of means for permitting only a limited movement of said car away from the landing while said door is open; substantially as described.

12. The combination with an elevator-car, power mechanism thereby, and a door, of means for permitting only a relatively slow limited movement of said car away from the landing while said door is open; substantially as described.

13. The combination with an elevator-car, power mechanism thereby, a controller for said power mechanism, and a door, of means for permitting only a limited movement of said controller while said door is open; substantially as described.

14. The combination with an elevator-car, power mechanism thereby, and a door, of means for automatically arresting the movement of said car should it travel a limited distance while said door is open; substantially as described.

15. The combination with an elevator-car, power mechanism thereby, and a door, of means for automatically reversing the movement of said car should it travel a limited distance while the said door is open; substantially as described.

16. The combination with an elevator-car, power mechanism thereby, and a door, of means whereby the car is placed under the control of the operator while it is at a landing adjacent said door and for a limited distance beyond said landing, and means for automatically arresting the travel of said car should it travel beyond said limited distance while the door is open; substantially as described.

17. The combination with an elevator-car, and power mechanism thereby, of a controller for said power mechanism, a door, and means for automatically operating said controller, said means being rendered inoperative while the door is closed but operative when the door is open; substantially as described.

18. The combination with an elevator-car, and power mechanism thereby, of a controller for said power mechanism, a door, and means for automatically operating said controller, said means being rendered inoperative while the door is closed and also inoperative to stop the travel of the car while the door is open and the car is within a limited distance of its landing, but said means being rendered operative while the door is open and after the car has traveled said limited distance; substantially as described.

19. The combination with an elevator-car, power mechanism thereby, a controller for said power mechanism, and a door, of a motor, and means for causing said motor to automatically control said controller at desired intervals of travel of the car; substantially as described.

20. The combination with an elevator-car, power mechanism thereby, and a door, of a motor, and means for causing said motor to control said car while the door is open; substantially as described.

21. The combination with an elevator-car, power mechanism thereby, and a door, of a motor, and means for causing said motor to control the movement of said car should it travel beyond a limited distance while said door is open; substantially as described.

22. The combination with an elevator-car, power mechanism thereby, and a door, of a motor, and means for causing said motor to control the movement of said car should it travel for a limited distance while the door is open, but to be inoperative with respect to said controlling action upon said car while the door is closed and while the car is in said limited distance and the door is open; substantially as described.

23. The combination with an elevator-car, power mechanism thereby, and a door, of a motor, and means for causing said motor to control the travel of the car while the door is open and to prevent the travel of the car should it move beyond a limited distance while the door is open; substantially as described.

24. The combination with an elevator-car, power mechanism thereby, a controller for said power mechanism, and a door, of a motor, and means for causing said motor to reverse the said controller should the car travel beyond a limited distance while the door is open; substantially as described.

25. The combination with an elevator-car, power mechanism thereby, a controller for said power mechanism, and a door, of a motor, and means for causing said motor to limit the effective setting of said controller while the door is open and to cause said motor to reverse said controller should the car travel beyond a limited distance while the door is open; substantially as described.

26. The combination with an elevator-car, power mechanism thereby, and a controller for said power mechanism, of means for automatically returning said controller in a position to produce only a limited speed should said controller be moved beyond said position; substantially as described.

27. The combination with an elevator-car, power mechanism thereby, a controller for said power mechanism, and a door, of a motor, and means for causing said motor to return said controller to a position to effect only a limited speed should said controller be moved beyond said position while the door is open; substantially as described.

28. The combination with an elevator-car, power mechanism thereby, a controller for said power mechanism, and a door, of means for permitting full control of said controller by the operator while the door is closed but only limited control of said controller by the operator while the door is open; substantially as described.

29. The combination with an elevator-car, power mechanism thereby, and a controller for said power mechanism, of a motor, means for engaging said motor, and means for operatively connecting said motor with said controller to cause said controller to operate the power mechanism in a direction tending to bring the car to rest; substantially as described.

30. The combination with an elevator-car, power mechanism thereby, and a controller for said power mechanism, of a motor, means for periodically engaging said motor, and means for operatively connecting said motor with said controller to cause said controller to operate the power mechanism in a direction tending to bring the car to rest; substantially as described.

31. The combination with an elevator-car, power mechanism thereby, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a motor, means for engaging said motor, gearing between said motor and said controller, and means for connecting and disconnecting said gearing; substantially as described.

32. The combination with an elevator-car, power mechanism thereby, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a motor, a worm driven by said motor, a segmented gear operatively connected to said controller, and means for connecting and disconnecting said worm and gear with relation to each other; substantially as described.

33. The combination with an elevator-car, power mechanism thereby, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a controller-shaft, a gear thereon, a motor, a shaft driven thereby, a gear upon said motor-driven shaft adapted to operatively engage said gear upon said controller-shaft, means for normally supporting said gear out of operative engagement, and means for throwing said gear into operative engagement; substantially as described.

34. The combination with an elevator-car, power mechanism thereby, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a controller-shaft, a gear thereon, a motor, a shaft driven thereby, a gear upon said motor-driven shaft adapted to operatively engage said gear upon said controller-shaft, means for yieldingly supporting said gear out of operative engagement, and means for throwing said gear into operative engagement; substantially as described.

35. The combination with an elevator-car, power mechanism thereby, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a controller-shaft, a gear thereon, an extended power-driven shaft, a gear on said power-driven shaft adapted to operatively engage said gear upon said controller-shaft, and a suitably-supported movable frame in which the free end of said power-driven shaft is journaled; substantially as described.

36. The combination with an elevator-car, power mechanism thereby, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a controller-shaft, a gear thereon, an extended power-driven shaft, a gear on said power-driven shaft adapted

to operatively engage said gear upon said controller-shaft, a suitably-supported movable frame in which the free end of said power-driven shaft is journaled, and a spring normally holding said frame in position to hold said gears out of operative engagement; substantially as described.

37. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a controller-shaft, a gear thereon, a motor, an extended armature-shaft, a gear on said armature-shaft adapted to operatively engage said gear upon said controller-shaft, and a suitably-supported movable frame in which the free end of said armature-shaft is journaled; substantially as described.

38. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a motor, means for automatically throwing said motor and said controller into operative engagement, and means for automatically throwing said motor and said controller out of operative engagement; substantially as described.

39. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a motor, gear connected to said motor and said controller, means for automatically causing operative engagement of said gears, and means for automatically throwing said gears out of operative engagement; substantially as described.

40. The combination with an elevator-car, power mechanism therefor, a controller for said power mechanism, and a door, of a motor normally out of operative engagement with said controller, means for automatically throwing said motor and controller into operative engagement when the said door is open, and means for throwing said motor and controller out of operative engagement when the door is closed; substantially as described.

41. The combination with an elevator-car, power mechanism therefor, a controller for said power mechanism, and a door, of a normally de-energized motor, means for operatively connecting said motor and said controller, and means for automatically energizing said motor when the door is open; substantially as described.

42. The combination with an elevator-car, power mechanism therefor, a controller for said power mechanism, and a door, of a motor normally de-energized and out of operative engagement with said controller, and means for automatically energizing said motor and throwing the same into operative engagement with said controller when said door is open; substantially as described.

43. The combination with an elevator-car, power mechanism therefor, a controller for said power mechanism, and a door, of a motor normally out of operative connection with said controller, means for automatically throwing said motor into operative connection with said controller should the travel of the car exceed predetermined limits when the door is open; substantially as described.

44. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a motor, gear connected to said motor and said controller, means for operatively connecting said gears, and means whereby the continued movement of said gears when connected causes the connection between said gears to be broken; substantially as described.

45. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, gearing between said motor and said controller, means for holding said gears in operative connection, means for disconnecting said gears by their continued movement, and means whereby the gear in connection with said controller can at times be moved to an extent corresponding to the full movement of said controller without affecting said disconnection but at other times will, by a movement not greater than said full movement of said controller, effect said disconnection; substantially as described.

46. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, gearing between said motor and said controller, means for holding said gears in operative connection, said parts being normally so related that movement of the gear in connection with said controller through a distance equal to the full throw of said controller fails to effect said disconnection, and means for altering the relation between said controller and its said gear whereby movement of said gear through a distance not greater than the full throw of said controller effects said disconnection; substantially as described.

47. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a controller-shaft, a motor, a gear operable by said motor, a gear loosely mounted on said

controller-shaft, means for holding said gear in operative connection, an arm upon said shaft adapted to be engaged by said gear when the latter is moved, and means upon said controller-shaft for breaking said connection in the movement of said gear, said gear having a limited amount of movement independent of said arm; substantially as described.

48. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable thereby, a controller-shaft, a gear loosely mounted thereon and having side members, means for holding said gear in operative connection, means upon said controller-shaft for breaking said connection during its movement, and an arm upon said controller-shaft and having a part extending between said side members of the gear, there being play between said side members and said part upon said arm; substantially as described.

49. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable thereby, a controller-shaft, a gear loosely supported upon said shaft, means for holding said gear in operative connection, means upon said gear carried by said shaft for causing said connection to be broken, a stop upon said shaft adapted to be engaged by said gear supported upon said shaft, and means for yieldingly holding said gear out of engagement with said stop; substantially as described.

50. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable thereby, a controller-shaft, a gear loosely supported upon said shaft and having side legs, means for holding said gear in operative connection, means upon said gear supported by said shaft for causing said connection to be broken, a stop upon said shaft and extending between the legs of said gear, plungers engaging opposite sides of said stop and extending respectively through openings in said gear-legs, and springs about said plungers and bearing between their inner ends and said respective gear-legs, whereby said legs are yieldingly held out of engagement with said stop; substantially as described.

51. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, means for operatively connecting said motor and said controller, and means for rendering said motor inoperative with relation to said controller when the latter has been moved a predetermined distance by the action of the former; substantially as described.

52. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, means for operatively connecting said motor and said controller, and means whereby the continued action of said motor serves to render the same inoperative with relation to said controller when said controller has been moved a predetermined distance by the action of said motor; substantially as described.

53. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable by said motor, a gear connected to said controller, means for operatively connecting said gears, and means whereby said controller-gear for causing said gear to be thrown out of connection by the movement of said controller-gear; substantially as described.

54. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable by said motor, a gear connected to said controller, means for operatively connecting said gears, and a cam carried by said controller-gear for causing said gear to be thrown out of connection by the movement of said controller-gear; substantially as described.

55. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable by said motor, a gear connected to said controller, means for operatively connecting said gears, and means adjustably supported by said controller-gear for causing said gear to be thrown out of connection by the movement of said controller-gear; substantially as described.

56. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable by said motor, a gear connected to said controller, means for yieldingly holding said gear out of connection with each other, a member adapted to engage a part connected to one of said gears and bring said gear into connection with said other gear against the action of said yielding means, and means for throwing said member out of position to effect said connection; substantially as described.

57. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable by said motor, a gear connected to said controller, means for yieldingly holding said gear out of connection with each other, a member adapted to engage a part connected to one of said gears and bring said gear into connection with said other gear against the action of said yielding means, and means for throwing said member out of position to effect said connection by the continued action of said gear; substantially as described.

58. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable by said motor, a gear connected to said controller, means for yieldingly holding said gear out of connection with each other, a member adapted to engage a part connected to one of said gears and bring said gear into connection with said other gear against the action of said yielding means, and a cam carried by said controller-gear and, in the continued movement of said gear, adapted to engage said member and throw the same out of position to effect said connection of said gears; substantially as described.

59. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable by said motor, a gear connected to said controller, means for yieldingly holding said gear out of connection with each other, a back adapted to engage a part connected to one of said gears and bring said gear into connection with said other gear, and means acting in synchronism with said gear for throwing said back out of engagement with said gear; substantially as described.

60. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable thereby, a gear connected to said controller, means for holding said gear out of connection with each other, a member having engagement with one of said gears, and means for moving said member for bringing said gear into connection with each other; substantially as described.

61. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a motor, a gear operable thereby, a gear connected to said controller, means for holding said gear out of connection with each other, an armature having connection with one of said gears, and a magnet for moving said armature to connect said gears; substantially as described.

62. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of means for causing said controller to operate the power mechanism in a direction tending to bring the car to rest, said means including a motor, a gear operable thereby, a gear connected to said controller, means for holding said gear out of connection with each other, an armature having connection with one of said gears, a magnet for moving said armature to connect said gears, and means for yieldingly holding said armature from said magnet; substantially as described.

63. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a gear operable thereby, a gear connected to said controller, means for yieldingly holding said motor-gear out of connection with said controller-gear, a magnet, an armature, means for yieldingly holding said armature away from said magnet, a back movably supported upon said armature, means for yieldingly holding said back in said engaging position, and a back upon said controller-gear adapted during the movement of said gear to move said back out of its said engagement; substantially as described.

64. The combination with an elevator-car, a power mechanism for use therewith, a single clutch controlling said power mechanism, and a plurality of doors, of means for operating said clutch by each of said several doors; substantially as described.

65. The combination with an elevator-car, a power mechanism for use therewith, and a shaft, of connection between said shaft and said power mechanism for controlling the latter by the rocking of the former, and means for operating said shaft by the movement of said door; substantially as described.

66. The combination with an elevator-car, a power mechanism for use therewith, and a shaft, of connection between said shaft and said power mechanism for controlling the latter by the rocking of the former, means for operating said shaft in one direction by the opening of said door, and means for reversely rocking said shaft as said door is closed; substantially as described.

67. The combination with an elevator-car, a power mechanism for use therewith, and a shaft, of connection between said shaft and said power mechanism for controlling the latter by the rocking of the former, a projection upon said shaft in the path of movement of said door whereby said shaft is rocked by the opening movement of said door, and a spring for rocking said shaft in the opposite direction when said door is closed; substantially as described.

68. The combination with an elevator-car, a power mechanism for use therewith, a single clutch controlling said power mechanism, a single movable member operatively connected to said clutch, and a plurality of doors, of means for operating said movable member by each of said several doors; substantially as described.

69. In an elevator mechanism or the like, a power mechanism, a clutch controlling the same, a plurality of independently-operable clutch-actuator sections, means for operating said clutch by the movement of any of said several sections; substantially as described.

70. In an elevator mechanism or the like, a power mechanism, a single clutch controlling the same, a plurality of independently-operable clutch-actuator sections, means for operating said clutch by the movement of any of said several sections; substantially as described.

71. In an elevator mechanism or the like, a power mechanism, a clutch controlling the same, a plurality of independently-operable clutch-actuator sections, and a common connector between said clutch and said sections and engaged by parts upon each of said sections, said engaged portion of said connector being movable with relation to one of said sections when engaged and moved by another thereof; substantially as described.

72. In an elevator mechanism or the like, a power mechanism, a clutch controlling the same, a plurality of independently-operable clutch-actuator sections, flanges upon said shaft-sections and provided with registering concentric slots, and a common connector between said clutch and said shaft-sections and having a member extending said slots, whereby the movement of one of said sections said member is engaged and moved but during said movement of said section said member plays in said slot of another of said sections; substantially as described.

73. In an elevator mechanism or the like, a power mechanism, a clutch-actuator, a suitably-supported perforated lag, a sliding rod extending through said lag, a clutch member upon said rod, a spring between said clutch member and said lag, a connection between said rod and said actuator, and means for moving said actuator against the action of said spring; substantially as described.

74. In an elevator mechanism or the like, a power mechanism, a clutch controlling the same and including a movable cross-band carrying contact members, a rod upon which said cross-band is carried, a suitably-supported perforated lag through which said rod is slidable, a spring between said cross-band and said lag, a movable clutch-actuator, and connection between said rod and said clutch-actuator; substantially as described.

75. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor for operating said controller, and a clutch in the circuit of said motor and operable by said controller; substantially as described.

76. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a relatively fixed terminal in said circuit, a controller-shaft, an arm carried thereby, and a terminal carried by said arm and adapted to cooperate with said relatively fixed terminal; substantially as described.

77. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a suitably-supported spring-pressed pivoted arm carrying a terminal of said motor-circuit, and a terminal of said circuit movable by said controller and adapted to contact with said first-mentioned terminal; substantially as described.

78. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, a normally open motor-circuit, and means for completing said circuit by the movement of said controller in either direction; substantially as described.

79. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor, and a motor-circuit including clutch members, one of which comprises two electrically-connected terminals while said other clutch member comprises a third terminal intermediate said other terminals, one of said clutch members being connected to and movable by said controller; substantially as described.

80. The combination with an elevator-car, and power mechanism therefor, of operative mechanism requiring reversal of movement, a motor for said operative mechanism, and means whereby upon reversal of movement of said car said motor is caused to operate to effect reversal of movement of said mechanism; substantially as described.

81. The combination with an elevator-car, and power mechanism therefor, of operative mechanism requiring reversal of movement, a motor for said operative mechanism, and means for reversing the movement of said motor upon reversal of movement of said car; substantially as described.

82. The combination with an elevator-car, and power mechanism therefor, of operative mechanism requiring reversal of movement, a motor for said operative mechanism, and means controlled by the movement of said car for automatically changing the direction of current through said motor; substantially as described.

83. The combination with an elevator-car, and power mechanism therefor, of operative mechanism requiring reversal of movement, a motor for said operative mechanism, a reversible shaft, connection between

said shaft and said car whereby the direction of rotation of the former is determined by the direction of movement of the latter, and means operated by said shaft for causing said motor to operate to effect reversal of said operative mechanism upon reversal of rotation of said shaft; substantially as described.

84. The combination with an elevator-car, power mechanism therefor, a rotatable shaft, and cables connected to said car and engaging said shaft, of a controller for said power mechanism, and means for causing reversal of said controller upon reversal of rotation of said shaft; substantially as described.

85. The combination with an elevator-car, power mechanism therefor, a rotatable shaft, and cables connected to said car and engaging said shaft, of a controller for said power mechanism, a motor for said controller, and means for causing said motor to operate to reverse said controller upon reversal of rotation of said shaft; substantially as described.

86. The combination with an elevator-car, power mechanism therefor, a rotatable shaft, and cables connected to said car and engaging said shaft, of a controller for said power mechanism, a motor for said controller, and means for causing reversal of movement of said motor upon reversal of rotation of said shaft; substantially as described.

87. The combination with an elevator-car, power mechanism therefor, and an operative mechanism requiring reversal of movement, of a motor for said operative mechanism, two open circuits including said motor, each of said circuits being adapted to direct current through said motor in a different direction, a member adapted to cooperate with the terminals of either of said circuits to complete said circuit, and means for causing contact between said member and the terminals of a different one of said circuits upon reversal of movement of said car; substantially as described.

88. The combination with an elevator-car, power mechanism therefor, and an operative mechanism requiring reversal of movement, of a motor for said operative mechanism, two open circuits including said motor, each of said circuits being adapted to direct current through said motor in a different direction, a member adapted to cooperate with the terminals of either of said circuits to complete said circuit, and means for shifting said member from the terminals of one of said circuits to those of the other thereof upon reversal of movement of said car; substantially as described.

89. The combination with an elevator-car, power mechanism therefor, and an operative mechanism requiring reversal of movement, of a motor for said operative mechanism, two open circuits including said motor each of said circuits being adapted to direct current through said motor in a different direction, a member having two terminals in connection with a source of electricity, and means whereby upon the reversal of movement of said car the terminals of said member are caused to contact with the terminals of a different circuit from the circuit-terminals with which they were in contact prior to said reversal of movement; substantially as described.

90. The combination with an elevator-car, and power mechanism therefor, of operative mechanism requiring reversal of movement, a motor for said operative mechanism, a rotatable shaft, connection between said car and said shaft whereby said shaft is caused to rotate by the movement of said car, the direction of rotation of said shaft being determined by the direction of movement of said car, and means whereby the direction of current to said motor is controlled by the rotation of said shaft; substantially as described.

91. The combination with an elevator-car, and power mechanism therefor, of operative mechanism requiring reversal of movement, a motor for said operative mechanism, a rotatable shaft, hoisting-cables connected to said car and passing over said shaft, and means whereby the direction of current to said motor is controlled by the rotation of said shaft; substantially as described.

92. The combination with an elevator-car, and power mechanism therefor, of operative mechanism requiring reversal of movement, a motor for said operative mechanism, a rotatable shaft, connection between said shaft and said car whereby the direction of rotation of the former is determined by the direction of movement of the latter, means for the motor, which circuits when completed send current through said motor in different directions, terminals for said motor-circuits, and a member adapted to engage either one of said circuit-terminals to complete the respective circuit, one of said elements (said circuit-terminals or said member) being carried by said shaft, and the other said element being in position to be engaged by said shaft-carried element; substantially as described.

93. In an elevator mechanism or the like, a rotatable shaft, means for rotating said shaft in reverse direction, operative mechanism, a motor therefor, an arm yieldingly engaged with said shaft to have its position changed by reversal of movement of said shaft, means for arresting the movement of said arm, and means carried by said arm for controlling the current to said motor; substantially as described.

94. In an elevator mechanism or the like, a rotatable shaft, means for rotating said shaft in reverse direction, operative mechanism, a motor therefor, an arm carrying means for controlling the current to said

motor, means for arresting the movement of said arm, and a spring holding said arm in yielding engagement with said shaft whereby the position of said arm is changed by reversal of movement of said shaft; substantially as described.

95. The combination with an elevator-car, and power mechanism therefor, of operative mechanism, and means for causing said mechanism to be engaged at points determined by the travel of said car; substantially as described.

96. The combination with an elevator-car, power mechanism therefor, and a landing to which said car travels, of an operative mechanism, and means for automatically engaging said mechanism when said car is substantially at said landing; substantially as described.

97. In an elevator mechanism or the like, a car, an interrupted series of contact-sections located along the path of travel of said car, a contact member carried by said car and having means for holding the same upon said contact-sections, an electric circuit including said contact-sections and said contact member, and an operative mechanism in said circuit, whereby said operative mechanism can be energized at intervals controlled by the movement of said car; substantially as described.

98. In an elevator mechanism or the like, a car, a track for a contact member and having live and dead sections, a contact member carried by said car and having means for holding the same upon said track, an electric circuit including said live track-sections and said contact member, and an operative mechanism in said circuit; substantially as described.

99. The combination with an elevator-car, power mechanism therefor, and an operative mechanism whose movement is designed to be reversed, of a motor for said operative mechanism, an electric circuit including said motor, and means for reversing the direction of the current through said motor; substantially as described.

100. The combination with an elevator-car, power mechanism therefor, and an operative mechanism whose movement is designed to be reversed, of a motor for said operative mechanism, an electric circuit including said motor, means for reversing the polarity of the field-magnet constant, and means for reversing the polarity of the armature of said magnet; substantially as described.

101. The combination with an elevator-car, and power mechanism therefor, of an operative mechanism requiring reversal of movement upon reversal of movement of said car, a motor for said operative mechanism, and means for changing the direction of current through said motor at every change of direction of travel of said car; substantially as described.

102. The combination with an elevator-car, power mechanism therefor, and a door, of mechanism for controlling said car, an electric circuit including said mechanism, a switch in said circuit, connection between said door and said switch whereby the latter is operable by the former, and a second switch in said circuit, said second switch being operated by a movement incident to travel of said car; substantially as described.

103. The combination with an elevator-car, power mechanism therefor, and a door, of a controller for said power mechanism, a motor for said controller, an electric circuit including said motor, a switch in said circuit and operable by the movement of said door, said motor-circuit being also controlled by said controller and by the movement of said car; substantially as described.

104. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a track having a dead section, a contact member carried by said car and engaging said track, an electric circuit including said track and contact member, an electric circuit including a switch operable by said controller, and a motor for said controller included in both of said circuits; substantially as described.

105. The combination with an elevator-car, power mechanism therefor, a controller for said power mechanism, and a door, of a track having a dead section, a contact member carried by said car and engaging said track, said dead section of track being so located that the said contact member engages the same when the car is at a landing, an electric circuit including said track and contact member, an electric circuit including a switch operable by said controller, a motor for said controller in both said circuits, a switch controlling both of said circuits, and connections between said latter-mentioned switch and said door for opening the former by the movement of the latter; substantially as described.

106. The combination with an elevator-car, power mechanism therefor, a controller for said power mechanism, and a door, of an electric circuit, a door-switch in said circuit, a motor in said circuit, means for holding said motor and said controller out of operative engagement, and a magnet in said circuit for bringing said motor and said controller into operative engagement; substantially as described.

107. The combination with an elevator-car, power mechanism therefor, a controller for said power mechanism, and a door, of an electric circuit, a door-switch in said circuit, a controller-switch in said circuit, a motor in said circuit, means for holding said motor and said controller out of operative engagement, and a magnet in said circuit for bringing said mo-

tor and said controller into operative engagement; substantially as described.

108. The combination with an elevator-car, power mechanism therefor, a controller for said power mechanism, and a door, of a track having a dead section, a contact member carried by said car and engaging said track, said dead section being so located that it is engaged by said contact member when said car is at a landing, an electric circuit including said track and contact member, a controller-switch, an electric circuit including said controller-switch, a motor for said controller and included in both of said circuits, means for holding said motor out of operative connection with said controller, a magnet in both of said circuits for bringing said motor and said controller into operative connection, and a door-switch in both of said circuits; substantially as described.

109. The combination with an elevator-car, power mechanism therefor, a controller for said power mechanism, and a door, of a track having a dead section, a contact member carried by said car and engaging said track, said dead section being so located that it is engaged by said contact member when said car is at a landing, an electric circuit including said track and contact member, a controller-switch, an electric circuit including said controller-switch, a motor for said controller and included in both of said circuits, means for holding said motor out of operative connection with said controller, a magnet in both of said circuits for bringing said motor and controller into operative connection, a door-switch in both of said circuits, a pole-changer controlling both of said motor-circuits, said means for operating said pole-changer by the movement of said car; substantially as described.

110. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor for operating said controller, and means for rendering said motor operative with relation to said controller upon movement of said controller; substantially as described.

111. The combination with an elevator-car, power mechanism therefor, and a controller for said power mechanism, of a motor for operating said controller, and means for rendering said motor operative with relation to said controller upon movement of said controller, said controller being permitted a limited movement without so rendering the said motor operative; substantially as described.

698,898. NUT-TAPPING MACHINE. THOMAS FINEY, Cleveland, Ohio. Filed Mar. 24, 1903. Serial No. 19,995. (No model.)

Claim.—1. In a nut-tapping machine, a frame, a tap, means for imparting rotary movement to said tap, a slide, a cam arranged to positively operate said slide in an intermittent backward and forward direction, in line with said tap, a nut holding and feeding carriage, operated independently of said slide and arranged to move in the path thereof, means substantially as described for holding the nut on said carriage while being tapped, means substantially as described for drawing the nut from said tap

and a spring mounted on said slide and arranged to exert a pressure upon said carriage when said slide is advanced toward the tap, substantially as described and for the purpose set forth.

2. In a nut-tapping machine, a tap, means for imparting rotary movement to the same, a work-carriage adapted to slide in a suitable support, a sliding bar located in juxtaposition to said work-carriage, a spring located in said sliding bar having one of its ends abutting against the end of said bar and its other end abutting against a lug projecting from the work-carriage, and means for intermittently reciprocating said sliding bar forward and backward, substantially as described and for the purpose set forth.

3. In a nut-tapping machine, a frame, a tap, a driving-spindle for operating said tap, a work-carriage mounted on said frame and adapted to slide thereon, a coiled spring having one end connected to said work-carriage and the other end connected to the frame in the rear of said carriage, a lug depending from said work-carriage, a shaft mounted beneath said driving-spindle, gear-wheels operatively connecting said shaft and said driving-spindle, a cam keyed to said shaft below said work-carriage, a slide between said work-carriage and said cam and operatively connected with said cam, and an elastic medium forming an operative connection between the said slide and the said work-carriage.

4. In a nut-tapping machine, a tap-carrying spindle, suitably-operated driving mechanism for imparting a rotary movement to said spindle, suitably-operated mechanism for reversing the rotary movement of said spindle, a work-carriage adapted to feed the nut onto the tap and draw it off from the tap, and means for operating said work-carriage, comprising a cam rotatably mounted below said work-carriage, a slide located between said work-carriage and said cam and operatively connected with said cam, and an elastic medium forming an operative connection between the slide and the said work-carriage.

5. In a nut-tapping machine, a frame, a tap, a driving-spindle for operating said tap, a work-carriage mounted on said frame and adapted to slide horizontally thereon, a coiled spring having one end connected to said work-carriage, and the other end connected to the said frame in the rear of said work-carriage, and a positively-driven slide operatively connected to said work-carriage by means of a yielding connection located between said carriage and said slide, substantially as described and for the purpose set forth.

6. In a nut-tapping machine, the combination with a work-carriage of a device for supplying blanks to said work-carriage, comprising a receptacle secured to springs mounted upon a support located in proximity to said work-carriage, a discharge-conduit leading from said receptacle to said work-carriage, the mouth of said discharge-conduit being located so as to be closed by the upper surface of the work-carriage except when the work-carriage is in its furthest back position, an opening formed in the side of said discharge-conduit, a slide normally closing said opening, a toothed wheel mounted in proximity to said receptacle, means for rotating said toothed wheel, and a lug depending from said receptacle and adapted to engage the teeth of said wheel, substantially as described and for the purpose set forth.

698,899. MACHINE FOR BORING BRUSH-BLOCKS AND CUTTING IN THE BRISTLES. CARL E. FLEMMING, Schönbühl, Germany. Filed June 24, 1904. Serial No. 61,572. (No model.)

Claim.—1. In a machine for boring brush-blocks and cutting in the bristles, the combination with the work-tables *a b*, of rods *c* supporting said tables, ball-joints *d f* supporting said rods, slides *g r* taking around the said rods and being adapted to be moved one rectilinearly to the other, and means for thus operating said slides, substantially as described.

2. In a machine for boring brush-blocks and cutting in the bristles, the combination with the work-tables *a b*, of rods *c* supporting said tables, ball-joints *d f* supporting said rods, a traverse *g* carrying said ball-joints, slides *g r* taking around the said rods and being adapted to be moved one rectilinearly to the other in a horizontal direction, means for thus operating said slides, and other means for lifting or lowering said traverse, substantially as described.

3. In a machine for boring brush-blocks and cutting in the bristles, the combination with the work-tables *a b*, of rods *c* supporting said tables, ball-joints *d f* supporting said rods, slides *g r* taking around the said rods and being adapted to be moved one rectilinearly to the other, ball-joints *e* inserted between the rods and said slides, and means for displacing the latter independently from one another in a horizontal direction, substantially as described.

4. In a machine for boring brush-blocks and cutting in the bristles, the combination with the work-tables *a b*, of rods *c* supporting said tables, ball-joints *d f* supporting said rods, slides *g r* taking around the said rods and being adapted to be moved one rectilinearly to the other, pairs of parallel bars *e p p* supporting said slides, vertical standards *h i h i* supporting said bars, and dovetailed elbow-joints connecting said standards

with the said bars, and means for displacing the said slides upon said pairs of parallel bars, substantially and for the purpose as described.

698,880. PNEUMATIC DISPATCH TUBE. EDWARD A. FORTY, Chicago, Ill. Filed Feb. 14, 1902. Serial No. 94,164. (No model.)

Claim.—1. In a pneumatic-tube system, the combination with an overhead main-line tube adapted to transmit carriers from an outlying station to the cash-desk, of a looped branch connected with and depending from said main-line tube at a local sending-station, a valve at the junction

of said main tube and branch normally deflecting the current through the latter but permitting the uninterrupted travel of through-carriers past the junction, and a sending-terminal located in said looped branch, substantially as described.

2. In a pneumatic-tube system, the combination with an overhead main-line tube adapted to transmit carriers from an outlying station to the cash-desk, of a looped branch connected with and depending from said main-line tube at a local sending-station, a valve at the junction of said main tube and branch normally deflecting the current through the latter but permitting the uninterrupted travel of through-carriers past the junction, and a double-trapped sending-terminal located in that branch of the loop through which the current descends, substantially as described.

3. In a pneumatic-tube system, the combination with a main-line tube adapted to transmit carriers from an outlying station to the cash-desk, of a branch tube communicating with said main-line tube, a sending-terminal in said branch tube, and means located in said branch tube for turning the carrier and for each while on route through the latter, substantially as described.

4. In a pneumatic-tube system, the combination with an overhead main-line tube adapted to transmit carriers from an outlying station to the cash-desk, of a looped branch connected with and depending from said main-line tube at a local sending-station, said branch comprising two parallel tubes lying close together and connected at their lower ends by a pocket, a valve at the junction of said main tube and branch normally deflecting the current through the tubes and pocket of the latter but permitting the uninterrupted travel of through-carriers past the junction, a sending-terminal located in that branch of the loop through which the current descends, and means located in said pocket serving, upon the descent of the carrier, to automatically transfer the carrier laterally into line with the outgoing branch of the loop, substantially as described.

5. In a pneumatic-tube system, the combination with an overhead main-line tube adapted to transmit carriers from an outlying station to the cash-desk, of a looped branch connected with and depending from said main-line tube at a local sending-station, said branch comprising two parallel tubes lying close together and connected at their lower ends by a pocket, a valve at the junction of said main tube and branch normally deflecting the current through the tubes and pocket of the latter but permitting the uninterrupted travel of through-carriers past the junction, a sending-terminal located in that branch of the loop through which the current descends, and a rocker pivoted in the bottom of the loop adapted to receive the descending carrier and to be tilted by the impact thereof to bodily transfer the carrier laterally into line with the outgoing branch of the loop, substantially as described.

6. In a pneumatic-tube system, the combination with an overhead main-line tube adapted to transmit carriers from an outlying station to the cash-desk, of an air-tight casing interposed in said main tube above a local sending-station, said casing having a horizontal passage-way therethrough in line with the main tube, and a pair of oppositely-curved depending passage-ways communicating at their upper ends with said horizontal passage-way, a looped branch containing a sending-terminal and connected to and communicating with the depending curved passage-ways of the casing, and a current-deflecting valve consisting of a plate pivotally mounted between the side walls of the casing above the path of carrier therethrough and having unequal areas exposed to the effect of the current on opposite sides of its pivotal axis, substantially as described.

698,881. COUPLING FOR CABLE-DRIVEN. GEORGE E. GARDNER, Providence, R. I., assignor to Gardner Manufacturing Company, Providence, R. I. Filed Jan. 2, 1902. Serial No. 97,967. (No model.)

Claim.—1. The combination with a tubular constrictor or similar article, of a tubular dowel, openings in the cylindrical wall of the dowel, clamps having radial movement in the openings, and spring-pressed cams acting on the clamps to hold them against the wall of the socket, as described.

2. In a coupling, the combination with a socket and the article to be secured in the socket, of a tubular dowel, longitudinal slots in the cylindrical wall of the dowel, disks in the opposite ends of the dowel, a central post, cam-rings on the post, a coiled spring bearing on the cam-disks, and radially-moving clamps operated by the spring-pressed cam-rings to bear on the wall of the socket, as described.

11. In a curving-machine, the combination of test-holder, a beam supporting the test-holder, a speed beam, vertical guides for the first beam fixed to the speed beam, means for lifting the first beam relatively to the second, and means for raising the second beam.

22. In a carving-machine, the combination of tool-holders arranged in pairs, two slides each carrying one tool-holder of each pair, means for simultaneously moving the slides in opposite directions, means for simultaneously inclining the tool-holders of each pair toward or away from each other, a table supporting the slides, a pivot for the table, means for turning the table about its pivot, a beam supporting the pivot, a second

beam, counterbalanced lever pivoted to the second beam and supporting the first, a pawl carried by one of the levers, a rack with which the pawl engages, and means for lowering the rack.

698,883. OPTOMETER. FRANK A. HART, Evanston, Ill. Filed July 24, 1901. Serial No. 60,798. (No model.)

Claim.—1. An optometer having, in combination, a lens, a distance-piece, a graduated beam, a target mounted to slide upon the beam, a slide also mounted to slide upon the beam, and controllable means for fixing the slide on the beam, said slide having a surface adapted to indicate upon the beam the graduation corresponding with the face of the target, substantially as described.

2. An optometer having, in combination, a lens, a distance-piece, a graduated beam, a target mounted to slide upon the beam, and a slide also mounted upon the beam, said slide having a surface adapted to be brought to the plane of the face of the target, substantially as described.

3. An optometer having, in combination, a lens of known refracting power, a distance-piece for holding the eye at one principal focus of the lens, a beam graduated to show units of refraction of said lens and with its zero-point at the other principal focus of the lens, a target mounted to slide on said beam, and a slide also mounted on the beam, said slide having means for indicating upon the beam the graduation corresponding with the face of the target, substantially as described.

4. An optometer having, in combination, a lens of known refracting power, a distance-piece equal to the focal length of the lens, a beam graduated to show units of refraction, the graduation falling opposite the principal focus of the lens being marked zero (0) and the other graduations being numbered in both directions from zero, a target mounted to slide on the beam, and a slide also mounted on the beam, said slide having means for indicating upon the beam the graduation corresponding with the face of the target, substantially as described.

698,884. DUST-PAN. WILLIAM L. HARRIS, Chicago, Ill., assignor of three-fourths to George H. R. French, George H. French, and Adin T. Howard, Chicago, Ill. Filed Dec. 25, 1901. Serial No. 57,148. (No model.)

Claim.—1. In a dust-pan of the character herein described, the combination of a pan-body, a hinged cover forming a dust-chamber at the rear of the same, a fixed handle member secured to the dust-pan body, and a movable handle member pivoted midway its length to the fixed handle member and operatively connected to the hinged cover at a point forward of the hinge connection of said cover to the body of the dust-pan, substantially as set forth.

2. In a dust-pan of the character herein described, the combination of a pan-body, a hinged cover forming a dust-chamber at the rear of the same, a fixed handle member secured to the dust-pan body, a movable

handle member pivoted midway its length to the fixed handle member and operatively connected to the hinged cover at a point forward of the hinge connection of said cover to the body of the dust-pan, and a spring-lever forming the pivotal connection between said handle members, substantially as set forth.

3. In a dust-pan of the character herein described, the combination of a pan-body, a hinged cover forming a dust-chamber at the rear of the same, a fixed handle member secured to the dust-pan body, a movable handle member pivoted midway of its length to the fixed handle member and operatively connected to the hinged cover at a point forward of the hinge connection of said cover to the body of the dust-pan, pendant pivot-cars on the movable handle member, and a spring-lever forming the pivotal connection between the handle members, substantially as set forth.

698,885. CIGAR-BUNCH-WRAPPING MACHINE. FLORENCE L. HARRISON, New York, N. Y., assignor to George L. McAlpin, New York, N. Y. Filed Feb. 27, 1901. Serial No. 58,000. (No model.)

Claim.—1. The combination with a cigar-bunch-wrapping mechanism, of a feed-hopper located in position to present the bunches to be wrapped within convenient reach of the operator, the said feed-hopper being provided with resilient discharge-jaws, substantially as set forth.

2. The combination with a cigar-bunch-wrapping mechanism including the group of rollers and wraps for lifting one of the rollers to receive a bunch to be wrapped, of a feed-hopper provided with a discharge-opening at the front in position to present a bunch within convenient reach of the operator, the said feed-hopper being provided with an actuating mechanism and means in connection with the roller-lifting means for operating said actuating mechanism as the roller is lifted to receive the bunch, substantially as set forth.

3. The combination with the cigar-bunch-wrapping mechanism, of a feed-hopper having resilient discharge-jaws, an actuating mechanism for

presenting bunches in the jaws in position to be removed and means for operating the agitating mechanism as the wrapping mechanism is operated to receive the bunch, substantially as set forth.

4. The combination with a cigar-bunch-wrapping mechanism, of a feed-hopper provided with resilient jaws for retaining the bunches in position to be grasped by the operator, a reciprocating riddle-plate within the hopper for agitating the bunches and means for operating the plate, substantially as set forth.

5. The combination with a cigar-bunch-wrapping machine, of a hopper removably secured to the machine and provided with an agitating mechanism and means in connection with the machine for operating the agitating mechanism, the agitating mechanism being arranged to move into and out of the path of the said operating means as the hopper is adjusted and removed, substantially as set forth.

6. The combination with the wrapping mechanism and means for lifting one of the rollers out of wrapping position of a movable bearing-piece for the tip of the bunch and means for operating the movable bearing-piece simultaneously with the lifting of the roller, substantially as set forth.

7. The combination with the wrapping mechanism and means for swinging the top roller away from the remaining rollers, of a swinging bearing-piece for the tip of the bunch and a weighted arm having a sliding-connection with the swinging roller-support for operating the said bearing-piece simultaneously with the movement of the roller, substantially as set forth.

8. The combination with the rolling mechanism, of a rocking support for one of the lower rollers, a retracting-spring for holding the said support in its normal position and an operating-lever arranged to operate the swinging support when moving in one direction and pass itself along the said support when moving in the opposite direction, substantially as set forth.

9. The combination with the rolling mechanism and means for swinging an upper roller upwardly out of position to receive a bunch, of a rocking support for one of the lower rollers, the said support having a substantially upright normal position, a spring for holding the rocking support in its normal position, a cut-away for regulating the rocking movement of the support and hence the roller and means for rocking the said support and hence the roller at the completion of the rolling operation, substantially as set forth.

10. The combination with the rolling mechanism, of an upper roller mounted to swing upwardly out of rolling position, a lower roller mounted to swing forwardly out of rolling position, a foot-treadle and means engaged with the foot-treadle for simultaneously operating the said upper and lower rollers, substantially as set forth.

11. The combination with the wrapping mechanism, of trimming-knives and means for moving them bodily in a direction lengthwise of the bunch to be trimmed, substantially as set forth.

12. The combination with the wrapping mechanism, of trimming-knives and means for simultaneously moving them bodily in a direction lengthwise of the bunch and transversely toward the bunch, substantially as set forth.

13. The combination with the wrapping mechanism, of trimming-knives arranged to move bodily in a direction lengthwise of the bunch and of a compression-spring in position to engage a bulb-blade to press it against its companion blade, substantially as set forth.

698,886. MOTOR-VEHICLE. WALLACE L. HUNT, Boston, Mass.
Filed July 27, 1901. Serial No. 69,886. (No model.)

Claim.—1. In a motor-vehicle, a main frame, a steering-frame, and a connecting-frame, a vertical pivotal bolt attaching said main frame to said connecting-frame, a horizontal pivotal bolt attaching said connecting-frame to said steering-frame, a pair of wheels arranged to rotate upon axle-bearings fast to said main frame, a rotary axle arranged to rotate in bearings fast to said steering-frame, a pair of wheels fast to said rotary axle, and a steering-wheel arranged to rotate in bearings in a swivel-frame, said swivel-frame arranged to swivel in bearings upon said steering-frame.

2. In a motor-vehicle, a main frame, a steering-frame, and a connecting-frame, a vertical pivotal bolt attaching said main frame to said connecting-frame, a horizontal pivotal bolt attaching said connecting-frame to said steering-frame, a pair of wheels arranged to rotate upon axle-bearings fast to said main frame, a rotary axle arranged to rotate in bearings fast to said steering-frame, a pair of wheels fast to said rotary axle, and a steering-wheel arranged to rotate in bearings in a swivel-frame, said swivel-frame arranged to swivel in bearings upon said steering-frame, in combination with a motor fast to said steering-frame and operatively connected to said rotary axle.

3. In a motor-vehicle, a main frame, a body supported thereon, a steering-frame pivotally connected to said main frame in such a manner that said frames may assume varying angles with relation to each other

in a horizontal and in a vertical plane, a motor supported upon said steering-frame, and a hood attached to said body and forming a covering for said motor and steering-frame.

4. In a motor-vehicle, a main frame, a body supported thereon, a steering-frame pivotally connected to said main frame in such a manner that said frames may assume varying angles with relation to each other in a horizontal and in a vertical plane, a motor supported upon said steering-frame, and a hood having a flexible front attached to said body and forming a covering for said motor and steering-frame.

698,887. MUT-LOCK. GEORGE A. HAY and JOHN J. FURMAN, Shamokin, Pa. Filed Jan. 15, 1902. Serial No. 69,814. (No model.)

Claim.—1. A nut-lock comprising a washer, a nut provided with a recess having overhanging walls, and a locking device associated with the washer and having spring-arms adapted to engage the said walls.

2. A nut-lock comprising a washer provided with a plurality of openings, a nut provided with a recess having overhanging walls, and a locking device having a part to interlock with the openings of the washer and with resilient members to engage the said recess.

3. A nut-lock comprising a washer provided with a plurality of openings communicating with a circumferentially-arranged channel in the lock thereof, a nut provided with a recess having overhanging walls, and a two-membered locking device adapted to engage with the said walls, one of the said members being provided with a toe to interlock with one of the openings in the washer and to project within the said channel.

4. A nut-lock comprising a washer provided with means for holding it against rotation and with a plurality of radially-disposed slots, a nut provided in one of its faces with a recess having overhanging walls, and a locking device having a toe to project within one of the openings and resilient locking members to engage the said walls.

5. A nut-lock comprising a washer provided with means for holding it against rotation and with a plurality of radially-disposed openings

communicating with a circumferentially-arranged channel in its tank; a nut provided in one of its faces with a means having overhanging walls, and a locking device having a toe to project through one of the openings and to lie in the channel and resilient arms to engage the walls of the said room.

698,888. TUTORIAL DEVICE. JAMES A. LAMER, New York, N. Y., assignor to American Lithographic Company, a Corporation of New York. Filed Feb. 8, 1902. Serial No. 38,398. (No model.)

Claim.—1. In a device of the character described, the combination with a base-section, of an upright section, said upright section being curved so as to maintain an upright position, said sections being connected together so as to retain the upright section in its curved form.

2. In a device of the character described, the combination with a base-section, of an upright section, said upright section being curved so as to maintain an upright position, and connections between said sections, said connections consisting of tongues and slots so arranged as to retain the upright section in its curved form.

3. In a device of the character described, the combination with a base-section, of an upright section, said upright section being curved so as to maintain an upright position, and connections between said sections, said connections consisting of tongues on the upright section and slots in the base-section, the slots being so disposed that when the tongues are inserted therein the upright section will be retained in its curved form.

4. In a device of the character described, the combination with a base-section, of an upright section, said upright section being connected at or near the opposite ends of its lower edge to the base-section at points on the latter which are nearer together than are the points of connection on the upright section, whereby the upright section is flared so as to maintain an upright position and is retained in its flared condition.

5. In a device of the character described, the combination with a base-section, of an upright section, said upright section having depending tongues at or near the opposite ends of its lower edge and said base-section having slots which are nearer together than are the tongues on the upright section, whereby the upright section when connected to the base-section is flared so as to maintain an upright position.

6. In a device of the character described, the combination with a base-section, of an upright section, said upright section being curved circumferentially and provided at its lower end with radially-projecting tongues connected to said base-section.

7. In a device of the character described, the combination with a base-section, of an upright section, said upright section being curved circumferentially and provided at its lower end with radially-projecting tongues connected to said base-section.

698,889. BLAST-FURNACE-FILLING APPARATUS. JULIAN KIMMERT, Pittsburgh, Pa. Filed Apr. 19, 1901. Serial No. 64,093. (No model.)

Claim.—1. A blast-furnace having an inclined track leading to its top, with an overhanging cantilever portion, a bell, and bell-operating mechanism supported on said cantilever; substantially as described.

2. A blast-furnace having an inclined track leading to its top, with an overhanging cantilever, a plurality of bells and bell-operating cylinders mounted upon the overhanging cantilever extension and connected to the bell, at least one of the cylinders being above and in line with the axis of the bell; substantially as described.

3. A blast-furnace having a charging bell and hopper, and a cylinder arranged to raise and lower the bell and connected thereto, said cylinder having at one movement a stroke of sufficient length to lift the bell above the blast-furnace top for replacing it; substantially as described.

4. A blast-furnace having a charging bell and hopper, and a motive cylinder above and in line with the axis of the bell and connected thereto, said cylinder having at one movement a stroke of sufficient length to lift the bell entirely above the top of the furnace; substantially as described.

5. A blast-furnace having a charging bell and hopper, a motive cylinder above the bell and containing a plunger carrying at its upper end connections leading downwardly to the bell, a valve-controlled source of non-freezing liquid under pressure leading to the cylinder, and a casing including the plunger and the upper part of its connection; substantially as described.

6. A blast-furnace having a charging-out, a motive cylinder connected thereto, said cylinder having a plunger, an oil-pocket at the head

of the cylinder, a cross-head carried on the plunger and a rod extending from the cross-head down through the pocket and connected to the bell; substantially as described.

7. A blast-furnace having a bell, and a motive cylinder having a plunger connected to said bell, said cylinder having a stationary casing or cover extending upwardly from its head and containing a cross-head with rods extending down to the cylinder connection; substantially as described.

8. A blast-furnace having a bell-operating cylinder containing a plunger, an annular liquid-receiving pocket surrounding its head portion, and a stationary casing surrounding the pocket and arranged to induce the plunger in its movement; substantially as described.

9. A blast-furnace having a bell-operating cylinder provided with packing, and having a liquid-pocket arranged to receive the liquid from the packing, and a drip-pipe leading from the pocket down to near the ground-level; substantially as described.

10. A blast-furnace having a bell-operating cylinder provided with a liquid-receiving room around its head, a plunger within the cylinder, and a hollow post in the room through which extends a rod connected to the plunger; substantially as described.

11. A blast-furnace having a bell-operating hydraulic cylinder provided with a cross-head secured to the plunger, rods depending from the cross-head, guide-channels through which the rods extend, and means for adjusting the cylinder laterally and changing its adjusted position; substantially as described.

12. A blast-furnace having a main bell and hopper, and a supplemental bell and hopper, a motive cylinder operating each bell, and means for connecting both bells to one of said cylinders; substantially as described.

13. A blast-furnace having a main bell and hopper and a supplemental bell and hopper, motive cylinders having cross-head connections with said bells, and detachable locking devices for securing the cross-heads together; substantially as described.

698,840. METHOD OF OPERATING BLAST-FURNACE. JULIAN KIMMERT, Pittsburgh, Pa. Filed May 3, 1901. Serial No. 68,099. (No model.)

Claim.—1. The method of preventing the discharge of coke after a dip, in a blast-furnace, consisting in reducing the area of the gas-escape when the charge in the furnace is hanging; substantially as described.

2. The method of operating a blast-furnace, consisting in reducing the area of the gas-escape when the pressure increases in the furnace; substantially as described.

3. The method of controlling a blast-furnace and preventing accidental discharge, consisting in throttling down the outlet and shutting back the gas-pressure when a dip occurs; substantially as described.

698,840.

698,841. CONTROLLER. GEORGE J. KLINE, Washington, D. C. Filed July 2, 1901. Serial No. 68,801. (No model.)

Claim.—1. A controller for governing the application of power, comprising means for communicating motion, a hollow rod connected to the same, means passed transversely through said rod for locking the same, means carried by said rod designed to engage said locking means, and a key extending longitudinally of said rod, and carried thereby inside the same and projecting from the upper end thereof and movable longitudinally for releasing the engagement of said lock-engaging means, substantially as described.

2. A controller for governing the application of power, comprising a lever for applying and shutting off said power, a handle at the upper end of said lever adapted to be grasped for operating the same, means passed transversely through said lever for locking the same, means carried by said rod designed to engage said locking means and a key projecting from within and carried by said handle and movable longitudinally thereof for releasing the engagement of said lock-engaging means, whereby said key is in position to manually fall beneath the thumb of the operator's hand, when the said handle is grasped, substantially as described.

3. A controller for governing the application of power, comprising a pivoted hollow rod, means for automatically locking said rod against movement, a lock-plate passed through said rod and designed to be engaged by said locking means within said rod, and means projecting from within the upper end of said rod for controlling said locking means substantially as described.

4. A controller for governing the application of power, comprising a pivot-pin for imparting motion, a hollow rod connected to said pin

locking means passed transversely through said rod, means carried within said rod for automatically engaging said locking means, and a key for operating said engaging means, substantially as described.

5. A controller for governing the application of power, comprising a pivot-pin for imparting motion, a hollow rod secured to said pin, a belt carried within said rod, a locking-plate passed through said rod and belt, means for holding said belt in contact with said locking-plate, whereby said rod will be locked against movement, and means for forcing said belt out of contact with said locking-plate, substantially as described.

6. A controller for governing the application of power, comprising means for imparting motion, a hollow rod carrying said means, a belt carried within said rod, a locking-plate passed through said rod and belt, means for automatically holding said belt in contact with said locking-plate, means for locking said belt against movement, and means for automatically releasing the same, substantially as described.

7. A controller for governing the application of power, comprising in its construction means for imparting motion, a hollow rod secured to said means, a belt carried within said rod, a locking-plate passed through said rod and belt, means for automatically maintaining said belt in contact with said locking-plate, a spring-pressed belt threaded into the upper end of said first-mentioned belt, said hollow rod being provided with a horizontal and a vertical slot situated near the top of said rod, a key carried by said spring-pressed belt adapted to operate in said slot, the upper end of the spring-pressed belt being of polygonal shape, a key provided with an aperture in its end adapted to register with said polygonal end, and a key carried by said key, the said hollow rod being provided with a vertical slot-opening at the upper end of said rod, a horizontal slot communicating therewith and another vertical slot leading downward from the inner end of the horizontal slot, the key of said key being adapted to be guided by said last-mentioned slot, substantially as described.

8. A controller for governing the application of power, comprising means for communicating motion, a hollow rod carrying the same, a belt within said rod, a lock-plate provided with a notch and passed through said rod and belt, means for normally holding said belt in engagement with said notch, a key for disengaging the same, means for retaining said key in engagement with said belt when the belt is not fully within said notch, and means for partially filling said notch for preventing the disengagement of said key from said belt, substantially as described.

9. A controller for governing the application of power, comprising a lever, means for imparting motion therefrom, a notched locking-plate engaged by said lever, a key for disengaging said lever from said plate, means for retaining said key in engagement with said lever until the same is brought into engagement with the notch of said lever, and an automatically-controlled pin adapted to partially fill said notch for preventing the disengagement of said key from said lever, substantially as described.

10. A controller for governing the application of power, comprising a lever, a notched locking-plate adapted to be engaged thereby, means for releasing such engagement, means retaining said releasing means in engagement with said lever until the said lever is brought fully into engagement with the notch of said locking-plate, and means for partially filling said notch for preventing disengagement of said releasing means from said lever, comprising a spring carried by said locking-plate, a pin held by said spring normally with its inner end within the notch of said plate, and means for locking said pin against the pressure of said spring, with its inner end free of said notch, substantially as described.

11. A controller for governing the application of power, comprising a lever, a notched locking-plate adapted to be engaged thereby, means for releasing such engagement, means for retaining said releasing means in engagement with said lever until the said lever is brought fully into engagement with the notch of said locking-plate, and means for partially filling said notch for preventing disengagement of said releasing means from said lever, comprising a housing carried by said locking-plate, a spring within said housing, a dotted head at the outer end of said housing, a pin extending longitudinally of said housing and pressed by said spring, whereby the inner end is normally held within the notch of said locking-plate, means for removing the inner end of said pin from said notch against the pressure of said spring, and a key adapted to move in the slot of said housing-head, and to engage the outer end thereof, when the said pin is partially rotated, for maintaining said pin with its inner end free of said notch, substantially as described.

12. A controller for governing the application of power, comprising a pivoted hollow rod, a belt movable within the same for locking said rod against movement, a detachable key inserted in the upper end of said rod and contacting with said belt for controlling the operation thereof, and means for preventing the removal of said key, substantially as described.

13. A controller for governing the application of power, comprising a pivoted hollow rod, a belt longitudinally movable within the same, a locking-plate passed transversely through said rod and belt, and means for causing said belt to engage said locking-plate for locking said rod against movement, substantially as described.

14. A controller for governing the application of power, comprising a pivoted, hollow lever, having a longitudinal, shouldered slot in its wall, means for locking said lever against movement, a key movable longitudinally within said lever at the upper end thereof for controlling said locking means, means carried by said key designed to engage the said shouldered slot for locking the key against removal, and means for permitting the removal of said key, substantially as described.

15. A controller for governing the application of power, comprising means for communicating motion, a rod connected thereto, a bolt movable within said rod for substantially locking the same against movement, means for preventing the unlatching of said bolt, a key projecting from the upper end of said rod for releasing the bolt, and means on said key engaging said rod for preventing the removal of the key, substantially as described.

16. A controller for governing the application of power, comprising a hollow rod for imparting motion, locking means passed transversely through said rod, means movable longitudinally within said rod for substantially engaging said locking means, and a key detachably engaging said rod and containing with said engaging means for operating the same, substantially as described.

17. A controller for governing the application of power, comprising a hollow rod, locking means passed through said rod, a bolt movable longitudinally within said rod, a spring inclosed by said rod pressing said bolt normally retaining the same in engagement with said locking means, and means detachably carried by said rod for moving said bolt against the pressure of said spring, substantially as described.

698,842. GABLE-GRIFF. JOHN HEDGECOCK and THOMAS BELL, Executors, Pa. Filed Oct. 12, 1891. Serial No. 74,176. (No model.)

Claim.—1. In a cable-grip, the combination with the body portion thereof having vertical slots therein, a screw-threaded shoulder, a stationary jaw having at its lower end a curved hook, a movable jaw connected to the cable having a concave lower surface and an elongated slotted upper surface, a detachable plate secured to the movable jaw over the slotted plate, a screw-bolt passing with screw-threads of the shoulder and with the detachable plate, and a head at the lower end of said bolt seated in said elongated slot, substantially as specified.

2. In a cable-grip, the combination with the body portion thereof having vertical slots therein, a screw-threaded shoulder at the upper end of the body portion, a stationary jaw secured to the shoulder having vertical slots and a curved hooked end, of a movable jaw connected to the cable of the stationary jaw and having a concave lower surface and an elongated slotted upper surface, a detachable plate secured to the movable jaw over the elongated slot, a screw-bolt passing with the screw-threads of the shoulder and with said detachable plate and means at the lower end of said screw-bolt seated in and adapted to operate in the said elongated slot, a coupling device connected to said shoulder and a lever connected to said screw-bolt to operate the movable jaw, substantially as specified.

698,843. RAILROAD-SPIKE. WILLIAM C. HARRIS, Clinton, Mich. Assignor of one-third to Jacob W. Harris, Aberdeen, Wash. Filed July 22, 1891. Serial No. 74,177. (No model.)

Claim.—A railway-spike having a laterally-projecting head, a pyramidal point, a neck rectangular in cross-section and twisted in a helix, and a neck shoulder in cross-section and tapering into the head.

698,844. WAGON-SKEIN. ALFRED L. MOORE, Melrose, N. H. Filed Sept. 11, 1891. Serial No. 74,178. (No model.)

Claim.—1. In a wagon-skein, the combination of a hollow body portion adapted to be mounted upon an axle, a cylindrical sleeve adapted to form a wheel-bearing removably and non-rotatably mounted thereon and provided with an annular flange upon its inner end for forming an end bearing, an extended screw-threaded end upon the body portion of the skein, and a nut mounted thereon and provided with an annular shoulder for forming opposite the shoulder formed by the flange on end bearing, substantially as described.

2. In a wagon-skein, the combination of a body portion adapted to be mounted upon an axle, a cylindrical sleeve removably and non-rotatably mounted upon said body portion, an annular flange integral with said sleeve, and means for connecting the annular flange to the shoulder on the body portion, substantially as described.

3. In a wagon-skein, the combination of a body portion adapted to be mounted upon an axle and provided with an annular shoulder and an extended screw-threaded end, a threaded nut mounted upon the threaded end of said body portion and provided with an annular shoulder, a removable steel sleeve non-rotatably mounted upon the body portion between the shoulder and the nut, an integral annular flange upon one end of the sleeve, and means for connecting the annular flange to the shoulder, substantially as described.

698,845. ACTUATING MECHANISM FOR KEY-OPERATED MACHINERY. DONALD MURRAY, New York, N. Y. Filed June 20, 1891. Serial No. 68,598. (No model.)

Claim.—1. The combination in actuating mechanism for key-operated machines of a perforated tape, a sprocket-wheel for advancing said tape, a suitable die-plate, a friction device consisting of a pair of spring-pressed plates between which the tape passes and a lever making yielding contact with said tape at a point between said friction device and wheel.

2. The combination in actuating mechanism for key-operated machines of a perforated controlling-tape, a sprocket-wheel for advancing the tape, a suitable die-plate, a friction device to restrain the tape and a spring-pressed lever to hold the tape taut.

3. The combination in the described mechanism of a sprocket-wheel, a perforated tape, and a yielding clutch device in position to underdrive the tape and vary its position on the wheel.

4. The combination in an actuating mechanism for key-operated machines of a perforated controlling-tape, a sprocket-wheel, a die-plate, and means for stopping the tape along the space between two successive perforations consisting of a radial arm on the wheel-shaft and a cap on said arm in position to underdrive the tape.

698,846. CURTAIN AND DRAPEY BEACON. DANIEL MCCARTHY and WILLIAM E. MCCARTHY, North Adams, Mass. Filed Nov. 14, 1891. Serial No. 68,599. (No model.)

Claim.—1. In a device of the kind described, the combination with the supporting-bracket, of the rod connecting said bracket, the depending longer-bracket having a dove at its upper end, its lower end being projected forwardly and having round and polygonal openings, and the pole-support-attached to the end bracket and having its outer end curved to receive the drapery-pole, substantially as described.

2. The combination with the supporting-bracket, of the rod connecting said bracket, the depending longer-bracket having a dove at its upper end and an apertured supporting-arm at its lower end, shoulders intermediate its ends, and the pole-support curved at its outer end to receive the pole and connected to the end bracket at its inner end, substantially as shown and described.

698,847. TAPPEY. WALLACE McNEAL and ALBERT McNEAL, Chicago, Ill., and CHARLES D. TROSBACH, Orem Valley, Cal. Filed Jan. 21, 1891. Serial No. 68,600. (No model.)

Claim.—1. A tappet comprising a body having a longitudinal bore and a longitudinal slot extending throughout the length thereof, a clamping member adapted to shut into said slot, means extending transversely through said clamping member and upper-body for removably securing said member to said body, and means for latching said body to a shaft.

2. A tappet comprising a body having a longitudinal bore and a slot extending throughout the length thereof, a clamping member adapted to shut into said slot, screw-bolts extending through said clamping member and tappet-body, said body having a recess disposed therein diametrically opposite said slot, a key-blank disposed in said recess, and keys adapted to extend through said body and clamp said blank to a stem or shaft.

698,848. FIRE-SCREEN GATE. JAMES W. McLENNAN, St. Louis, Mo.; Leo A. McLENNAN, administrator of said James W. McLENNAN, deceased. Filed June 22, 1891. Serial No. 68,601. (No model.)

Claim.—1. The combination, in a fire-screen gate, of a fire-frame having hinged members A A, and lock-catch v, affixed to the back side of the frame at the fire edge, a fire-screen mounted on arm and elbow hinged A B, to be united to the hinged members on the frame, the arm v v and elbow g g affixed to said hinges on indented rim for the passage of hinge-arms, and the lock F affixed to the screen to cooperate with the lock-catch on the frame, all substantially as set forth.

2. A fire-screen gate comprising a catch and a hinged screen having an indentation, a lock-plate therein, a lock having a knob carrying a pin and push-button, a hollow handle affixed to the knob, spring members and a stop member, movable within said handle and having a rod and tumblers to be operated by said push-button, said spring members cooperating with the catch above mentioned; all substantially as shown.

698,849. SCRAPER FOR FLOORS. DR. CLOVIS GUILLIOTTE, Lowell, Mass. Filed Sept. 14, 1891. Serial No. 74,179. (No model.)

Claim.—1. A tool of the character stated comprising a working member, clamping members formed to confine the said working member, a handle, and connections between the clamping members and the handle, said connections including a socket and a filling-piece therefor, and having provision for rigidly securing the clamping members and the blade to the handle at various angles.

2. A tool of the character stated comprising a working member, clamping members formed to confine the said working member, an expandable socket connected with the clamping members and adapted when expanded to lock the clamping members and working member together, and a handle having an expandable socket-filling piece on which the socket is adapted to turn to give the working member various angular adjustments, and means for expanding said filling-piece and socket.

3. A tool of the character stated comprising a working member, such as a blade, outer and inner clamping members bearing on opposite sides of the blade, a two-part adjustable socket, one part of which is attached to one clamping member while the other part is attached to the other clamping member, a handle having a two-part adjustable filling-piece located between said socket parts, and means for extending said filling-piece to cause it to elongate the two-part socket and thereby cause the clamp members to grasp the blade.

4. A tool of the character stated comprising a working member, such as a blade, outer and inner clamping members bearing on opposite sides of the blade, a two-part adjustable socket, one part of which is attached to one clamping member, while the other part is attached to the other clamping member, a handle having a two-part adjustable filling-piece located between said socket parts, and means for extending said filling-piece to cause it to elongate the two-part socket and thereby cause the clamp members to grasp the blade, the said socket and filling-piece being formed to permit a relative adjustment of the socket-parts and clamp members relatively to each other, whereby the clamp members and the blade held thereby may be caused to the handle at different angles.

5. A tool of the character stated comprising a working member, such as a blade, outer and inner clamping members bearing on opposite sides of the blade, a two-part adjustable socket, one part of which is attached to one clamping member, while the other part is attached to the other clamping member, a handle composed of two independently-movable members terminating in a two-part adjustable filling-piece located between said socket parts and connectedly connected, so that the filling-piece may

be elongated by a given adjustment of the handle members and caused to engage the clamping members with the blade.

6. A tool of the character stated, comprising a working member, such as a blade, outer and inner clamping members bearing on opposite sides of the blade, a two-part adjustable socket, one part of which is attached to one clamping member while the other part is attached to the other clamping member, a handle having a two-part adjustable filling-piece located between said socket parts, and means for extending said filling-piece to cause it to elongate the two-part socket and thereby cause the clamping members to grasp the blade, said blade being rotatably adjustable between the clamping members to present either of its edges to the surface to be scraped.

7. A tool of the character stated, comprising a working member, such as a blade, outer and inner clamping members bearing on opposite sides of the blade, a two-part adjustable socket, one part of which is attached to one clamping member, while the other part is attached to the other clamping member, a handle having a two-part adjustable filling-piece located between said socket parts, and means for extending said filling-piece to cause it to elongate the two-part socket and thereby cause the clamping members to grasp the blade, one of said clamping members having a guard formed to project over one edge of the blade.

8. A tool of the character stated, comprising a working member, such as a blade, outer and inner clamping members bearing on opposite sides of the blade, a two-part adjustable socket, one part of which is attached to one clamping member, while the other part is attached to the other clamping member, a handle having a two-part adjustable filling-piece located between said socket parts, and means for extending said filling-piece to cause it to elongate the two-part socket and thereby cause the clamping members to grasp the blade, said blade having a hand held adapted to detachably engage one of its edges.

9. A tool of the character stated, comprising an acting member, such as a blade, outer and inner clamping members bearing on opposite sides of the blade, a two-part adjustable socket, one part of which is attached to one clamping member while the other part is attached to the other clamping member, a handle composed of two independently-movable members terminating in a two-part adjustable filling-piece located between said socket parts and concentrically connected, so that the filling-piece may be elongated by a given adjustment of the handle members and caused to engage the clamping members with the blade, and means for locking the handle members together to maintain the filling-piece in its elongated adjustment.

10. A tool of the character stated, comprising an acting member, such as a blade, outer and inner clamping members bearing on opposite sides of the blade, a two-part adjustable socket, one part of which is attached to one clamping member, while the other part is attached to the other clamping member, a handle composed of two independently-movable members terminating in a two-part adjustable filling-piece located between said socket parts and concentrically connected, so that the filling-piece may be elongated by a given adjustment of the handle members and caused to engage the clamping members with the blade, one member of the handle having a projection and the other member a recess adapted to engage said projection to lock the handle members together.

11. A tool of the character stated, comprising a blade, outer and inner clamping members bearing on opposite sides of the blade, the inner member having a member of a two-part socket, a loop attached to the other clamping member and forming a complementary part of said two-part socket, a handle composed of two independently-movable members terminating in loops located in said loop and concentrically connected, said loops projecting into the said socket and forming an adjustable filling-piece between the parts of the socket, said filling-piece being elongated by a given adjustment of the handle members, and caused to engage the clamping members with the blade.

12. A tool of the character stated, comprising a blade, outer and inner clamping members bearing on opposite sides of the blade, the inner member having a member of a two-part adjustable socket, a belt passing through said members and blade and engaged at one end with the outer member and having at the other end a loop forming a complementary part of said two-part socket, a handle composed of two independently-movable members terminating in loops located in said loop and concentrically connected, said loops projecting into the said socket and forming an adjustable filling-piece between the parts of the socket, said filling-piece being elongated by a given adjustment of the handle members and caused to engage the clamping members with the blade.

13. A tool of the character stated, comprising a working member, such as a blade, outer and inner clamping members bearing on opposite sides of the blade, a two-part adjustable socket, one part of which is attached to one clamping member, while the other part is attached to the other clamping member, a handle having a two-part adjustable filling-piece located between said socket parts, and means for extending said filling-piece to cause it to elongate the two-part socket and thereby cause the clamping members to grasp the blade, the said tool having means for locking the handle members together to maintain the filling-piece in its elongated adjustment.

ing-piece to cause it to elongate the two-part socket and thereby cause the clamping members to grasp the blade, the said tool having means for holding a brush.

698,850. ARTIFICIAL FUEL. WILLIAM R. FRANK, Vineyard Haven, Mass. Filed Sept. 26, 1901. Serial No. 74,590. (No specimen.)
Claim.—A compound to be used in connection with fire-wood and consisting of arsenic, salt, lime vitriol, charcoal, sulfur and copper in the proportions set forth.

698,851. GATE. EDWARD PHILLIPS, Newport, Ark. Filed May 22, 1901. Serial No. 81,599. (No model.)

Claim.—The combination is a gate structure, of the spaced post members 4, 5, provided with sliding slots at their upper portions, a follower-block 19 guided in said slots and extending longitudinally beyond the outer sides of the post members, the ends of the follower-block being transversely extended beyond the adjacent walls of the slots to prevent endwise movement of the follower-block, transversely-disposed bars 22, arranged one on each side of the spaced posts and secured thereto, two-part levers extending from a point near the base of the post to the outer ends of the bars 22, securing-bolts uniting the ends of the bars and levers, levers 25 and 26 pivoted on said securing-bolts and having their inner ends projecting within the slots of the post members, links extending from the inner ends of said levers to a central eye or loop on the follower-block, gate-supporting rollers 8 and 9 carried by one of the post members, and a gate-structure comprising a substantially rectangular main-gate section adapted to close the gateway-opening and an inner braced angular portion extending beyond the spaced posts and carrying partly to counterbalance the weight of the main-gate section, said gate being supported by the lower roller 8 and being guided by the upper roller 9, an additional roller 14 journaled at the extreme inner end of the extended portion and adapted for travel in contact with the under side of the top rail of the fixed frame, and a connecting-bar 3 pivotally connected at one end to the under side of the follower-block and at the opposite end to the upper central portion of the main-gate structure, substantially as specified.

698,852. SLIDING DOOR. GEORGE A. FRANK, New Britain, Conn., assignor to F. & F. Quinn, New Britain, Conn., a Corporation of Connecticut. Filed Jan. 16, 1902. Serial No. 69,890. (No model.)

Claim.—1. An improvement in sliding doors, comprising a pair of doors, a rack carried by each of said doors, a swinging connection therefor, and a barrel-shaped pinion meshing with said racks whereby the motion of one is transmitted to the other, and a carrying device for said pinion.

2. An improvement in sliding doors, comprising a pair of doors, a pivoted rack carried by each of said doors, and a pinion meshing with said racks whereby the motion of one is transmitted to the other, and a carrying device for said pinion.

3. An improvement in sliding doors, comprising a pair of doors, a rack carried by each of said doors, and a pinion meshing with said racks whereby the motion of one is transmitted to the other, and a carrying device for said pinion, said carrying device being slidably mounted and having lateral movement relatively to the line of movement of said racks.

4. An improvement in sliding doors, comprising a pair of doors, a rack carried by each of said doors, and a pinion meshing with said racks whereby the motion of one is transmitted to the other, and a carrying device for said pinion, said carrying device including a cage slidably movable in a bracket and means carried by said cage to hold its ends in mesh with said pinion.

5. An improvement in sliding doors, comprising a pair of doors, a rack carried by each of said doors, and a pinion meshing with said racks

whereby the motion of one is transmitted to the other, and a carrying device for said pinion, said carrying device including a cage slidably movable in a bracket and rollers carried by said cage to hold the racks in mesh with said pinion.

6. An improvement in sliding doors and the like comprising a pair of doors, a U-shaped rack attached to each of said doors and a pinion for mutual engagement with said racks.

7. An improvement in sliding doors and the like comprising a pair of doors, a U-shaped rack attached to each of said doors and a barrel-shaped pinion for mutual engagement with said racks.

698,853. STEEL-ROD-POLE. EMERY C. FROST, New York, N. Y. Filed Dec. 12, 1900. Serial No. 69,891. (No model.)

Claim.—1. An eye-glass-polishing device, consisting of a case composed of two flexible separate divider side members integrally united by a narrow central joining portion to form a hinge, said members being provided with a rim, and at the edges thereof opposite the hinge with fastening devices, and flexible pulleys similar in form to the side members of the case and of less dimensions than the said side members and adapted to fit in said case, said pulleys being secured at the narrow central portion to the hinged portion of the side members of the case, substantially as shown, and described.

2. An eye-glass-polishing device consisting of a casing composed of two separate divider divider members of flexible material united at one edge to form a hinge and each of which is provided with a rim and flexible pulleys similar in form to the side members of the casing and of less dimensions adapted to fit in said casing, said pulleys being secured at one side and being also secured at the point of their connection to the hinged portion of the case, said hinged members of the case being provided at their free edges with catches, substantially as shown and described.

698,854. EXTENSIBLE FULCRUM. JOHN C. FRANK, Hartford, Conn., assignor of one-half to Arthur L. Foster, Hartford, Conn. Filed Mar. 16, 1901. Serial No. 81,599. (No model.)

Claim.—1. The combination of two plates of a sliding and a fixed pulley of the class described, one on each of said shafts, and a driving connection between them; said shafts comprising a hub fixed on the shaft, smaller side plates one on each side of said hub, loose on the shaft, and interlocking means between the hub and the plates, whereby the latter may rotate independently of the hub and shaft; arms between the

plates pivoted by their inner ends on the hub and their outer ends having a sliding engagement with the plates; peripheral segments on the outer ends of said arms, also located between the plates; spiral springs engaging by one end each of said plates, and by the opposite ends secured to the shaft; means for adjustably separating said shafts and for rotating one of them, substantially as described.

2. In an extensible and contractible pulley, a shaft, a wheel-hub fixed thereon, smaller plates constituting the sides of the wheel located on said shaft, one each side of said hub, and loose on the shaft, interlocking means between said hub and plates whereby the latter may rotate relative to the shaft and hub; arms between the plates pivoted to said hub and having a sliding engagement with the plates, V-shaped peripheral segments on said arms and a lining in said segments, such as leather, and means for securing said lining; a spiral spring on each side of said pulley and engaging one plate of the latter by one end and secured to the shaft by the opposite end, and means for rotating the shaft, substantially as described.

3. In an extensible and contractible pulley or wheel, a shaft, a wheel-hub fixed thereon, smaller plates constituting the sides of the wheel located on said shaft on each side of, and close to said hub and loose on said shaft, arms between said plates pivoted to said hub by one end, said latter end being curved to conform substantially to the hub, radial grooves in the inner surfaces of said plates with which the opposite ends of said arms engage, and peripheral segments on said arms, a spiral spring, one of whose ends is in engagement with one of said plates, and whose opposite end is in engagement with a member secured to said shaft, whereby the movement of said plates rotating on the shaft will compress said spring, substantially as described.

698,855. NEEDLE-THREADER. GEORGE FRANK, Aachen, Germany. Filed Nov. 12, 1901. Serial No. 82,167. (No model.)

Claim.—1. The combination, in a needle-threader of the class described, of a body portion having a substantially L-shaped opening at or near one end in which the upper wall of the body is lower than the body of the threader.

2. The combination, in a needle-threader of the class described, of a

head, a body portion having a substantially L-shaped opening at one end and in which the upper wall of the head is lower than the body portion.

2. A needle-threader of the class described, consisting of a body piece or bar of rectangular cross-section, having a substantially L-shaped opening at one end, in which the opening is placed at right angles to the longer axis of the bar, and the opening extends along said axis toward the nearer end.

698,856. PLASTIC COMPOUND AND METHOD OF MANUFACTURING SAME. LEONARD M. RABOCHIN, Newark, N. J., assignor of three-fifths to Samuel C. Bruno and Lawrence F. Bruno, Brooklyn, N. Y. Filed Sept. 5, 1901. Serial No. 74,464. (No specimens.)

Claim.—1. The plastic compound herein described, composed of a waste product from the manufacture of varnish, japan and shellac and known as varnish residue, powdered peat and old rubber material, substantially as set forth.

2. The plastic compound herein described and composed of waste product from the manufacture of varnish, japan and shellac and known as varnish residue, about twenty-five per cent. of powdered peat and about twenty per cent. of old rubber material, substantially as set forth.

3. The method of manufacturing the plastic compound herein specified, consisting in taking a given quantity of a waste product from the manufacture of varnish, japan and shellac, and known as varnish residue, heating the same hot and draining the same through a cloth or similar material for the removal of foreign substances, adding thereto in a heated condition a given quantity of powdered peat, stirring or mixing the same into a homogeneous mass, adding thereto a given quantity of old rubber material dissolved in naphtha, allowing the said composition to dry out, then breaking up and grinding the same to a fine consistency for other use in heating and molding to form, substantially as set forth.

698,857. ELEVATOR. JAMES RICE, Chicago, Ill., assignor of two-thirds to William H. Rice and William I. Rice, Chicago, Ill. Filed Mar. 28, 1901. Serial No. 65,778. (No model.)

Claim.—1. The combination of a liquid-containing chamber, a propeller therein, means for operating the same in said chamber and means mechanically connecting said propeller with the object to be elevated for imparting its propelling force thereto, substantially as set forth.

2. The combination of a liquid-containing chamber, a piston therein, a piston-rod connected to said piston, means located on one side of the piston and connected with said piston-rod for forcing the liquid in a direction away from the piston and thereby reacting on said rod, means for relieving the pressure on the other side of said piston, and means for operatively connecting said piston-rod with the object to be lifted, substantially as set forth.

3. The combination of a liquid-containing chamber, a propeller therein having blades, a piston having a piston-rod operatively related to said propeller and also located in said chamber, means for revolving said propeller and means for connecting said piston-rod to the object to be elevated, substantially as set forth.

4. The combination of a liquid-containing chamber, a piston having a rod therein, a by-pass around said piston, a valve for controlling said by-pass, a propeller in said chamber operatively related to said piston-rod, and means operatively relating said piston-rod to the object to be elevated, substantially as set forth.

5. The combination of a liquid-containing chamber, a valve piston having a rod therein, a by-pass around said piston, means for controlling said by-pass, a propeller operatively related to said piston-rod and having operative connection therewith with the object to be elevated and means for operating said propeller, substantially as set forth.

6. The combination of a liquid-containing chamber, a piston therein operatively related to the object to be elevated, a by-pass around said piston, a valve for controlling said by-pass, a propeller operatively related to the object to be elevated, an electric motor for operating said propeller, a magnet for controlling said valve, a switch for closing the circuit through either said motor or magnet and means for operating said switch, substantially as set forth.

7. The combination of a liquid-containing chamber, a propeller and a piston in said chamber, a motor for operating said propeller movable bodily therewith, a by-pass for permitting the water or liquid in said chamber to pass said piston and means for controlling said by-pass, substantially as set forth.

8. The combination of a liquid-containing chamber, a piston and a propeller therein, a piston-rod passing through said piston and connected to said propeller, and a motor for rotating said rod, substantially as set forth.

9. The combination of a liquid-containing chamber, a piston located in said chamber, a piston-rod connected to said piston, a propeller on said piston-rod located within said chamber, a truck, a motor mounted on said truck and operatively connected with the rod rotating said piston-rod, a shaft operatively connected with said truck, a fixed shaft and a cable passing around said shafts, substantially as set forth.

10. The combination of a liquid-containing chamber and a propeller having propelling blades or paddles located therein, one of said parts (the chamber and propeller) being movable with relation to the other by the propelling action of said blades or paddles, and means for connecting said movable part with the object to be lifted, substantially as set forth.

698,858. VISE ATTACHMENT. SAMUEL S. RICE, Ltd., E. Y. Filed July 25, 1901. Serial No. 65,657. (No model.)

Claim.—1. A vise attachment comprising a base-plate having a straight face, a sliding wedge having a straight face in contact with said plate and an opposite inclined face supported upon said plate for longitudinal movement in a straight path; substantially as specified.

2. A vise attachment comprising a base-plate, a sliding wedge supported upon said plate for longitudinal movement, and a spring-plate upon the outer face of said wedge; substantially as specified.

3. A vise attachment comprising a base-plate, a sliding wedge supported upon said plate for longitudinal movement, a spring-plate upon the outer face of said wedge, and means carried by said clamping-plate for securing the attachment to a vice-jaw; substantially as specified.

4. A vise attachment comprising a base-plate having a stop-pin at one end thereof, a sliding wedge carried by said plate and provided with a groove or way to receive said pin, a spring-plate secured to said base-plate and lying upon the outer face of said wedge, and means for connecting the base-plate to a vice-jaw; substantially as specified.

5. A vise attachment comprising a base-plate having a stop-pin at one end thereof, a sliding wedge carried by said plate and provided

with a groove or way to receive said pin, a spring-plate secured to said base-plate and lying upon the outer face of said wedge, a hooked portion provided at one end of said base-plate, and a clamping-jaw secured to said base-plate and provided with a hooked portion to engage a vice-jaw; substantially as specified.

6. In a vice attachment having a hooked portion at one end and a stop-pin at the opposite end, a clamping-plate provided with a hooked portion at one end and adjustably secured to said base-plate, a sliding wedge having a straight face to engage said base-plate and a groove or way therein to receive said stop-pin, opposite edge flanges extending from said wedge over the edge of the base-plate, and a spring-plate secured at one end to the base-plate and adjustably to fit in contact with the inclined face of said wedge; substantially as specified.

698,859. STYLOGRAPHIC PEN. WILLIAM W. RABOCHIN, Newark, N. J., assignor of one-half to Frederick D. Bennett, Freshford, N. J. Filed Oct. 2, 1901. Serial No. 71,771. (No model.)

Claim.—1. The combination in a stylographic pen, of an ink-reservoir, a weighted longitudinally-movable needle, and a hollow head in which said weighted needle moves adapted to close the lower end of said reservoir and provided with an air-passage having substantially right-angled bends which connects the interior of the head with the outer atmosphere at a point between the ends of the weighted portion of said needle, substantially as described.

2. The combination in a stylographic pen, of an ink-reservoir, a hollow head adapted to close the lower end of said reservoir, a hollow tip on said head provided with a capillary bore for the needle and with an air-passage having sharp-angled bends which connects the interior of said tip with atmosphere, and a weighted needle longitudinally movable in said head, substantially as described.

3. The combination in a stylographic pen, of an ink-reservoir, and a hollow head adapted to close the lower end of said reservoir and consisting of a sleeve having a side orifice which is adapted to establish communication between the said reservoir and the interior of said head, a hollow coupling, and a hollow tip having a capillary bore for the needle and a sharply-angled air-passage connecting the interior of said head with atmosphere, substantially as described.

4. In a stylographic pen, the ink-reservoir *a*, at the lower end of which is the hollow tip *b* provided with a capillary bore *c* for the needle and with groove *d* the outer groove *e* which connects with said groove *f* and the diametrically opposite hole *g* which connects the groove *c* with the interior of said tip *b*, substantially as described.

5. In a stylographic pen, the ink-reservoir *a*, the coupling *f* which is adapted to close the lower end of said reservoir, the sleeve *b* fitted into the upper end of said coupling *f* and provided with the slot *h* which connects the said ink-reservoir with the interior of said sleeve *b* and coupling *f*, and the hollow tip *c* which is fitted into the lower end of said coupling *f* and is provided with a capillary tube or bore *g* for the needle and with the groove *d* the outer groove *e* connecting with said groove *f* and the diametrically opposite hole *g* connecting said groove *c* with the interior of said tip *c*, substantially as described.

6. In a stylographic pen, the combination with the ink-reservoir and weighted needle, of the hollow tip *c* which is provided with a capillary tube or bore for the needle, a conically-ended chamber for the weight of the needle and a sharply-angled air-passage which connects the interior of said tip *c* with atmosphere at a point between the ends of the weighted portion of said needle, substantially as described.

7. The combination in a stylographic pen of an ink-reservoir, a hollow head adapted to close the lower end of said reservoir, a weighted needle longitudinally movable in said head, a chamber in said head having its lower end so shaped as to guide the needle-point into the capillary bore and to prevent the weight on said needle from quite reaching the bottom of said chamber, and an air-passage in said head, substantially as described.

8. The combination in a stylographic pen, of an ink-reservoir, a hollow head adapted to close the lower end of said reservoir, an air-passage

in said head from atmosphere to a chamber in said head, and a weighted needle movable in said head and with its weight on said needle so limited that the lower end of the weight thereof shall always be below the outlet of said air-passage, substantially as described.

9. The combination in a stylographic pen, of an ink-reservoir which is without an internal air-tube, a hollow head adapted to close the lower end of said reservoir and having a weighted needle longitudinally movable therein, and said head consisting of a sleeve having a side orifice which is adapted to establish communication between the said reservoir and the interior of said head, a hollow coupling, and a hollow tip having a capillary bore or tube for said needle, and a sharply-angled air-passage connecting the interior of said head with atmosphere and having the outlet thereof always above the lower end of the weight on said needle, and a chamber in said tip so shaped as to curve both to guide the needle into the capillary bore and to prevent the weight on said needle from quite reaching the bottom of said chamber, substantially as described.

10. The combination in a stylographic pen, of an ink-reservoir, a head-section at one end of the reservoir, a tube in said section cut away at the side and communicating with atmosphere, and a weighted needle movable in said section, substantially as described.

11. The combination in a stylographic pen, of an ink-reservoir, a head-section at one end of said reservoir, a channel connecting said reservoir with atmosphere, a tube in said section cut away at the side, and a weighted needle movable in said section, substantially as described.

12. In a stylographic pen, the combination of the sleeve *j* provided with the stem *i* and the slot *m*, and a needle provided with a weight vertically movable in said sleeve *j*, substantially as described.

698,860. TIRE. LOUIS B. SARKIS, Philadelphia, Pa. Filed Sept. 15, 1901. Serial No. 70,482. (No model.)

Claim.—1. A tire having a tread provided with a base and shoulder, upon which shoulder rests a piece of rigid material, portions of which run through the tire at the shoulders and are vulcanized in the mass comprising the tire, and a channelled plate adapted to receive said base and having its side portions engage said plate.

2. In a tire having a tread provided with a base and side shoulder and a channelled plate adapted to receive said base and provided with internal flanges which engage said shoulder, a piece of rigid material embedded in the tread and resting against said shoulder, the side portions of said channelled plate engaging said piece at said shoulder.

3. A tire consisting of a tread provided with a base and side shoulder, a channelled plate receiving said base and having internal flanges on the sides thereof, and a sheet frame of rigid material in said base resting against said shoulder and being engaged by said flanges.

4. A tire consisting of a tread provided with a base and side shoulder, a channelled plate receiving said base and having internal flanges on the sides thereof, a sheet frame of rigid material in said base resting against said shoulder and being engaged by said flanges, and a channelled rim receiving said plate and having the latter firmly connected therewith.

698,861. CORRUGATED CORRUG, WATER-SAIL, AND FOUNTAIN-STRIKER. JOHN P. GILMAN, Brooklyn, N. Y., assignor to Parker, Sherman & Gilman, New York, N. Y., a Corporation of New York. Filed Mar. 20, 1901. Serial No. 65,595. (No model.)

Claim.—1. A valve device for the purpose described, comprising a tubular plug, a hollow valve-carrying stem arranged to move in the plug and to control the passage of liquid therethrough, the outer end or ends of said stem being immediately adjacent to the outer end of the plug and substantially flush therewith so that a flexible pipe may be slipped over the adjacent outer ends of the plug and the stem, so as to cover the joint between said ends and prevent leakage.

3. The combination with a bag or receptacle having an outlet, a tubular stopper-plug in said outlet, a hollow valve-carrying stem arranged to move in the plug and to control the passage of liquid there-through, the outer end or nozzle of said stem being immediately adjacent to the outer end of the plug and substantially flush therewith, and a flexible pipe extending over the adjacent outer ends of the plug and of the stem, and covering the joint between said ends to prevent leakage.

698,862. WATCHMAN'S TIME-DETECTOR. JAMES SCHLIMMER, Schwabingen, Germany. Filed Nov. 25, 1901. Serial No. 65,666. (No model.)

Claim.—1. In a watchman's time-detector, the combination of a rotatable time-dial, with a marking-plate, having matrices provided thereon and capable of lateral movement, a key co-operating means carried by said marking-plate, and marking-bugs co-operating with said means and having marking-types on their end faces, substantially as set forth.

2. In a watchman's time-detector, the combination of a marking-plate adapted to have lateral movement and having matrices provided thereon, with marking-bugs provided with means for laterally moving said marking-plate and co-operating with said matrices, substantially as set forth.

3. In a watchman's time-detector, the combination of a rotatable time-dial, with a laterally-movable marking-plate arranged at one side thereof and having matrices provided thereon, a keyhole, a key co-operating means arranged in line with said keyhole and carried by said marking-plate, and marking-bugs adapted to engage said means and to impress said time-dial from the side opposite to said marking-plate, substantially as set forth.

4. In a watchman's time-detector, the combination of a marking-plate capable of lateral movement and having matrices provided on the center line thereof and at each side of said center line, with a roller carried by said marking-plate, and a marking-bug, having a side rib with an inclined surface, adapted to engage with said roller for moving said marking-plate, and having a marking-type on the end face thereof, substantially as set forth.

5. A watchman's time-detector, comprising a graduated time-dial rotated by a clock-movement, a push-down-lever, a spring for holding said push-down-lever in central position, a marking-plate provided with matrices mounted on the free or swinging end of said lever, a roller mounted on said lever in line with the center of the marking-plate and keyhole, and a plurality of bugs provided with projections or ribs on the sides and marking-types on the end faces, substantially as set forth.

6. A watchman's time-detector, comprising a graduated rotary time-dial, a spring-controlled push-down-lever suspended at one end and having an enlarged opening at the free opposite end, a marking-plate provided with matrices mounted on the free end of said lever, a roller supported in front of said plate on the free end of the lever, and a plurality of bugs provided with side projections or ribs of greater or lesser lengths and marking-types on their end faces, substantially as set forth.

698,868. VALVE-GEAR. OSCAR SCHMID and HOWARD A. FRANK, Columbus, Ohio. Filed June 1, 1901. Serial No. 65,707. (No model.)

Claim.—1. The combination with the steam-cylinder, of a piston working therein, said piston being hollow at each end and solid at the

center, a rod passed transversely through the piston and working through the sides of the cylinder, said rod or bar being operatively connected to the valve-stem, substantially as shown and described.

2. In a valve-gear, the combination with the cylinder and steam-chest, of the piston hollow at each end and solid at the center, the rod or bar passing through the solid portion of the piston and working in slots produced in the sides of the cylinder, the rod-chest, piston and operating arm for connecting the transverse rod or bar with the valve-stem, substantially as shown and described.

3. The combination with the cylinder closed longitudinally, of the piston hollow at each end and solid at the center, the transverse rod or bar passing through the solid portion of the piston and working in the slots of the cylinder, the piston-rod connected to the ends of the said transverse bar or rod by means of a yoke, the valve-stem, rod-chest, arm and piston, said arm being connected to the end of the transverse rod or bar whereby as the piston is reciprocated the valve is operated, substantially as described.

698,864. TYPE-WRITING MACHINE. HOWARD A. SHAFER, Hamroth, Pa. Filed Dec. 7, 1901. Serial No. 65,902. (No model.)

Claim.—1. In a carriage-return mechanism, the combination with a carriage, of a revolvable plate bearing a ratchet, a bell-crank lever mounted on said carriage and carrying a pawl pivoted to one arm thereof and limited to engage said ratchet, a bell attached to the other arm of said lever, and means constructed to be actuated by one face of the operator to pull said bell in opposite said lever to return said carriage, substantially as described.

2. In a carriage-return mechanism, the combination with a carriage, of a revolvable plate bearing a ratchet-wheel, a bell-crank lever mounted on said carriage and bearing a pawl on one arm limited to engage said ratchet, a bell connected to the other arm, a rod-chest connected to said bell, and an arm on said rod-chest positioned to be engaged by one face of the operator to actuate said bell to turn said plate and return the carriage, substantially as described.

3. In a carriage-return mechanism, the combination with a carriage, of a revolvable plate bearing a ratchet, a bell-crank lever mounted on said carriage and bearing on one arm a pawl limited to engage said ratchet, a bell connected to the other arm of said lever, a screw mounted on the frame of the machine and limited to engage said bell to hold it in line, and means for pulling said bell to return said carriage, substantially as described.

4. In a carriage-return mechanism, the combination with a carriage, of a revolvable plate bearing a ratchet, a bell-crank lever bearing a pawl pivoted to one arm thereof and engaging said ratchet, an adjustable stop mounted to engage said lever to control the throw thereof, and means connected to the other arm of said lever to operate it to revolve said plate and return said carriage, substantially as described.

5. In a carriage-return mechanism, the combination with a carriage carrying a revolvable plate provided with a ratchet, of a chair having two arms, a bell-crank lever pivoted on a plate and bearing projections, a pawl carried by said bell-crank lever, a stop adjustably mounted between said arms in position to engage one of said projections to regulate the throw of said lever and means for actuating said lever to operate said plate, substantially as described.

698,865. SUPPORT FOR HAMMOCK. OLAMBERT SMITH and JAMES L. HODGES, Philadelphia, Pa. Filed Apr. 8, 1901. Serial No. 64,908. (No model.)

Claim.—1. A plate, an outwardly-projecting base thereon, said base being open in front and rear and having a shoulder on its inner face around the front opening, a washer in said base seated on said shoulder, a hook, and an eye carrying the lower end having contracted flange which pass through said front opening of the base and through said washer and are

spread at the rear opening within said base, said base being integral with said plate.

2. In a support of the character stated, a plate, means for securing the same in position, an outwardly-projecting base on said plate, the same being open in front and rear, a hook in front of said base, an eye by which said hook is suspended, said eye being provided with flange which occupy said base and are partly contracted and partly spread apart, and a washer which is seated on the inner face of the wall of the front opening of said base and embraces the contracted portion of said flange.

698,866. VARIABLE-SPEED MECHANISM. JOHN A. SMITH, Baltimore, Md., assignor to Smith Lyrphane Company, a Corporation of West Virginia. Filed Apr. 22, 1901. Serial No. 65,957. (No model.)

Claim.—1. In a variable-speed mechanism, the combination with a revolvable body, of a ratchet-arm; a curved disk carried by said ratchet-arm and impinging against the revolvable body; a secondary shaft; means connecting the said disk and secondary shaft; and a lever to rock the said ratchet-arm to change the point of contact between the revolvable body and curved disk to vary the speed of the secondary shaft, substantially as and for the purpose set forth.

2. In a variable-speed mechanism, the combination with a revolvable body, of a ratchet-arm; a shaft vertically adjustable on said arm; a curved disk mounted on said shaft and impinging against the revolvable body; means to keep the said disk in contact with the revolvable body; a pulley carried by said disk; a secondary shaft; means connecting the said pulley and secondary shaft; and a lever to rock the said ratchet-arm to change the point of contact of the said disk with the revolvable body to vary the speed of the secondary shaft, substantially as and for the purpose described.

698,867. CONFIDEMENT-OUTTER. HYMAN A. SMITH, New York, N. Y., assignor to International Machine Co., New York, N. Y. Filed Dec. 16, 1900. Serial No. 65,975. (No model.)

Claim.—1. In a machine of the character herein specified, the combination with the reciprocable table and means for reciprocating the same, of the automatic material-feeding mechanism constructed as set forth; means for automatically regulating the amount of feed, and for automatically holding and stopping the feed, substantially as shown and described.

2. In a machine of the character herein specified, the combination with the reciprocable table and feeding mechanism carried thereby, of an actuating-shaft beneath the table, a sprocket loosely mounted upon said shaft, and operating mechanism connected to said sprocket, substantially as shown and described.

3. The combination with the reciprocable table and means for re-

ciprocating the same, of a holding-block adapted and arranged to be depressed by contact with a feed shaft beneath which it passes on the table reciprocates, substantially as shown and described.

4. The combination with the material-feeding mechanism, of a movable bar upon the material-carrying table engaging with said feeding mechanism, and connections between said bar and a ratchet-wheel which actuates the feeding mechanism.

698,868. TIE-TIGHTENER. JOHN E. SCOTT, Oakville, Ind. Filed June 20, 1901. Serial No. 65,955. (No model.)

Claim.—1. A tie-tightener, comprising a base, a screw-threaded standard rising therefrom, a sleeve mounted upon the standard, a rim-engaging head carried by the outer end of the sleeve, a polygonal wrench-head upon the sleeve, and a wrench, having a circular opening slidably and rotatably embracing the sleeve, and an enlarged polygonal wrench-head to detachably embrace the wrench-head.

2. A tie-tightener, comprising a base, a screw-threaded standard rising therefrom, an end-wise-adjustable sleeve mounted upon the standard, and provided at its outer end with a rim-engaging head, the inner end of the sleeve having a polygonal wrench-head, and a wrench, having a handle and an opening for the reception of the sleeve, one end of the opening being circular to rotatably and slidably embrace the sleeve, and the opposite end of the opening being enlarged and made polygonal to form a wrench-head for the detachable reception of the wrench-head.

3. A tie-tightener, comprising a two-part base, of which the lower part is bridge-shaped and provided with opposite intermediate transversely and downwardly inclined side portions, there being a detachable connection between the base members, a screw-threaded standard rising from the upper base-member, and an end-wise-adjustable sleeve rotatably mounted upon the standard, and having its outer end provided with a revolved rim-engaging head.

4. A tie-tightener, comprising a two-part base, opposite detachable side-plates thereon, each of which consists of a rotatable stem mounted

upon the lower base-section, and a crank-arm to overlap the adjacent portion of the upper base-section, the edge of the latter having a recess for the reception of the adjacent stem, a screw-threaded standard rising from the upper base-section, and an internally-screw-threaded sleeve mounted upon the standard, and provided at its outer end with a rim-engaging head.

688,869. REER-STOCKING APPARATUS. CHARLES SWANER, Jersey City, N. J. Filed Sept. 4, 1901. Serial No. 74,688. (No model.)

Claim.—1. A bear or other vat provided with a suitable inlet and a discharge-pipe provided with a discharge flange or valve and a seal and check-valve located between the discharge flange and valve and the vat, substantially as shown and described.

2. A bear or other vat provided with an air-inlet in the top thereof, a suitable inlet for bear or other liquids, a discharge-pipe at the bottom thereof provided with a valve, and a seal and check-valve placed between said discharge-pipe valve and the vat, substantially as shown and described.

3. A bear or other vat provided with an air-inlet in the top thereof, a suitable inlet for bear or other liquids, a discharge-pipe at the bottom thereof provided with a valve, and a seal and check-valve placed between said discharge-pipe valve and the vat, said air-inlet and said discharge-pipe being also provided with pipes which are in connection with a hot-steam-heating machine, substantially as shown and described.

4. A discharge-pipe for bear and other vats, provided with a discharge-valve, and a seal and check-valve placed between the discharge-valve and the end of the pipe which communicates with the vat, substantially as shown and described.

688,870. MANUFACTURE OF TUPED FABRICS. CHRISTIAN S. S. STONE, WILMINGTON, Pa., assignor of one-half to John Knechtel, WILMINGTON, Pa. Filed Mar. 11, 1900. Renewed Sept. 4, 1901. Serial No. 74,688. (No model.)

Claim.—1. An awl-base for use in making tuped fabrics by hand, said base having a plurality of clamping-awls set removably in its upper face in rows, substantially as and for the purpose set forth.

2. An awl-base having a substantially level upper surface of at-

least one end and said surface provided with holes arranged in rows to receive the awls, in combination with clamping-awls set removably in each of said holes as and in the desired cutting-points, substantially as set forth.

3. An awl-base for use in making tuped fabrics by hand, of the size and contour of the fabric to be made, said base having a plurality of counterbored holes or sockets in its upper face and at the cutting-points, and having removable clamping-awls, secured removably in said holes, each of said awls having an annular concavity in its upper face, substantially as set forth.

4. An awl-base for use in making tuped fabrics by hand, of substantially the size and contour of the fabric to be made, said base having cut in its upper face a plurality of awl-sockets or holes arranged in rows, removable awls set in each hole as correspond to the cutting-points, and pins or bolts of, set in the edge of said base at the ends of the rows of holes, substantially as set forth.

5. A device for making upholstery composed of a base and a plurality of detachable awls, adapted to clamp tub-bottom chairs.

6. A device for making upholstery composed of a flat base and a plurality of disk-like awls set detachably in the same and adapted to clamp the chairs of tub-bottoms.

688,871. BOTTLE-FILLING MACHINE. LOUIS SCHMIDT and CHARLES W. WILLIAMS, New York, N. Y., assignors to the Century Stopping Company, New York, N. Y., a Corporation of New York. Filed Jan. 18, 1902. Serial No. 90,904. (No model.)

Claim.—1. In a bottle-filling machine, the combination, with a rest for the bottle to be filled, of a vertically-movable stock above said rest, means for operating said stock, a stopper-gripper pivoted to said stock at the lower portion of the same, a discharge-nozzle carried by said gripper and arranged to discharge into the bottle when the gripper is in laterally-shifted position, and means for applying the liquid to be bottled to said discharge-nozzle, substantially as set forth.

2. In a bottle-filling machine, the combination, with a rest for the bottle to be filled, of a housing adapted to inclose the upper portion of the bottle, means for moving said housing in vertical direction, a vertically-movable stock having its lower portion located within the housing, means for operating said stock, a stopper-gripper pivoted to said stock within the housing, a discharge-nozzle carried by said gripper and arranged to discharge into the bottle when the gripper is in laterally-shifted position, and means for applying the liquid to be bottled to said discharge-nozzle, substantially as set forth.

3. In a bottle-filling machine, the combination, with a rest for the bottle to be filled, of a housing located above the rest and adapted to inclose the upper portion of the bottle, means for moving said housing in vertical direction, a tubular vertically-movable stock having its lower portion located within the housing, means for applying the liquid to be bottled to said tubular stock, means for operating said stock, a spring-act-

uated stopper-gripper pivoted to the stock within the housing, a discharge-nozzle carried by said gripper and arranged to discharge into the bottle when the gripper is in laterally-shifted position, and a flexible tube connecting said tubular stock with the discharge-nozzle, substantially as set forth.

4. In a bottle-filling machine, the combination, with a tubular vertically-movable stock, of a laterally-shiftable stopper-gripper pivoted to the same at its lower portion, a discharge-nozzle carried by said gripper and arranged to discharge into the bottle when the gripper is in laterally-shifted position, and a flexible tube connecting said discharge-nozzle and the stock, substantially as set forth.

5. In a bottle-filling machine, the combination, with a tubular vertically-movable stock, of a laterally-shiftable stopper-gripper pivoted to and adapted to abut against the same at its lower portion, a discharge-nozzle carried by said gripper and arranged to discharge into the bottle when the gripper is in laterally-shifted position, and a flexible tube connecting said discharge-nozzle and stock, substantially as set forth.

6. In a bottle-filling machine, the combination, with a vertically-movable stock, of a laterally-shiftable stopper-gripper pivoted to the same at its lower portion and comprising a body portion or chuck and a horizontal claw extending at an angle from the lower end of the chuck and having a stopper-receiving means arranged at an angle to the direction of movement of the gripper, and a discharge-nozzle carried by said claw and arranged to discharge into the bottle when the gripper is in laterally-shifted position, substantially as set forth.

7. In a bottle-filling machine, the combination of a stationary cross-bar, a rest for the bottle to be filled, vertically-movable slide-rod, means for actuating the same, a cross-frame pivoted to said slide-rod and adapted to abut when in lowered position against said rest, a screen on said cross-frame, an arm extending from said cross-frame, a rod connecting said arm with the cross-bar, and a spring-coil in said rod, substantially as set forth.

8. In a bottle-filling machine, the combination of a stationary cross-bar, vertically-movable slide-rod, means for actuating the same, a cross-head connecting said slide-rod, a housing supported on said cross-head, a screen-frame pivoted to said slide-rod, a screen on said screen-frame, said screen-frame being so pivoted as to swing the screen in downward direction beyond said housing, an arm extending from said screen-frame, and a rod connecting said arm with said cross-bar, substantially as set forth.

688,872. GARNET-CYLINDER. EDWIN J. VANCE, Philadelphia, Pa., assignor to the Philadelphia Textile Machinery Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed Jan. 28, 1902. Serial No. 90,904. (No model.)

Claim.—1. As a new article of manufacture, a garnet-cylinder having a cylindrical body, a shell of dentile and relatively soft material cast thereon, said shell having a continuous spiral groove from end to end, and having a continuous toothed strip wound in said groove, the ridges between successive convolutions of said strip being spread and in engagement with said strip, substantially as described.

2. As a new article of manufacture, a garnet-cylinder consisting of a supporting-cylinder, a shell of material having a relatively low melting-point surrounding the same, a continuous toothed metallic strip wound in a continuous groove in the surface of said shell, the inner edge of said strip being greater in section than the outer edge thereof, the material of said shell being spread so as to overlap the inner portion of said strip thereby retaining it in position, substantially as described.

688,873. SHOW-FLY. CHARLES L. TOLAN, San Diego, Cal. Filed Jan. 7, 1902. Serial No. 90,717. (No model.)

Claim.—1. The combination, with a suitable runner having a substantially-adjustable runner-section, of a rotating-wheel carried upon said adjustable section, and means for raising or depressing said adjustable runner-section, substantially as described.

2. The combination, with a suitable runner comprising a fixed sec-

tion, a vertically-adjustable section, of a rotating-wheel carried by said adjustable section and means for raising or depressing said adjustable section and thereby carrying the edge of the rotating-wheel above or below the lower edge of the other runner-section, substantially as described.

3. The combination, with a runner having a pivotally-supported and vertically-adjustable section, a rotating-wheel fixed thereon and means for lifting said adjustable section and thereby raising or lowering the cutting edge of said rotating-wheel, substantially as described.

4. The combination, with a sled-runner provided with a movable runner-section, of means for pivotally connecting the rear portion of said movable runner-section to said runner, means for raising or lowering the forward portion of said movable runner-section, and a rotating-wheel secured upon said movable runner-section, substantially as described.

5. The combination, with sled-runners provided in their forward portions with elongated openings, of a V-shaped plow arranged between said runners and adapted to discharge snow and ice laterally through said openings, means for vertically adjusting said plow, the vertically-movable runner-sections adjustably connected to said runners at the rear portions thereof and the rotating-wheel arranged upon said adjustable runner-sections, substantially as described.

6. The combination, with sled-runners provided at the forward portion, with elongated openings and at their rear portions with vertically-adjustable runner-sections, the V-shaped plow arranged between the forward portions of said runners, between said elongated openings, adjustable wings secured to the runners in the rear of said openings and in front of said adjustable runner-sections rotating-wheels secured upon said adjustable sections and means for raising or lowering said adjustable runner-sections, substantially as described.

688,874. FIVE-ROCK SHUT-OFF. JAMES E. TOWNS, New York, N. Y., assignor to T. & F. Curtis, New York, N. Y., a Corporation of Connecticut. Filed Jan. 7, 1902. Serial No. 90,718. (No model.)

Claim.—1. In a device of the character described, a frame, guide thereon, a pair of jaws each carried thereby and on said guide, a transverse passage in said frame forming a space between said jaws to readily

receive a hose-pipe, and means to operate said jaws to move them toward or away from each other.

2. In an apparatus of the character described, a frame composed of a pair of sections, guideways between said sections, blocks movable in said guideways, a transverse passage through said frame-sections and between the facing edges of said blocks, whereby the hose may be readily placed between the blocks, and means to move the blocks toward or away from each other, substantially as and for the purpose specified.

3. In a device of the character described, a frame, reciprocating blocks carried thereby, means to prevent the lateral or vertical displacement of said blocks, operating-handles pivotally attached to the frame, and means of connection between said handles and said blocks whereby the movement of the frame is transmitted to the latter, and a passage-way for hose or the like through said frame between the detached or facing edges of said blocks.

4. In an apparatus of the character described, a frame composed of a plurality of sections, guideways therein to receive reciprocating blocks the facing edges of said blocks being provided with jaws, a passage-way through said frame and between the facing edges of said blocks, operating devices comprising handles pivoted to the frame, cranks carried by said handles adjacent the pivotal connection, and links between said blocks and said cranks, substantially as and for the purpose described.

698,875. COMBINED WAIST-HOLDER AND SKIRT-SUPPORTER. FRANK W. TURNER, Hildford, Conn., assignor of one-half to John L. Boston, Lynn, Mass. Filed May 1, 1901. Serial No. 66,318. (No model.)

Claim.—A combined waist-holder and skirt-supporter comprising a belt having a pocket formed therein, a plate embedded within the pocket and provided with a plurality of double hooks, each double hook comprising a body portion having a point extended upwardly from the lower end of the body portion through the outer face of the belt for engaging the skirt and another point extended downwardly from the upper end of the body portion through the inner face of the belt for engaging the waist, one of the points of the hook being bent snugly into engagement with the plate at the base of the point to prevent the hook from turning and a tongue struck from the plate engaging the body portion of the hook to a point adjacent to the base of the other point to prevent the hook from shifting longitudinally, substantially as set forth.

698,876. BOLSTER FOR RAILWAY-CARS. CORNELIUS VAN DER BEEK, New York, N. Y. Filed Oct. 4, 1901. Serial No. 77,949. (No model.)

Claim.—1. A bolster for railway-cars, comprising a transverse member having an upper compression member with flanges, and a lower tension member with flanges, said members having their flanges placed side by side at the ends of the transverse member, and there secured together by means which pass through both beams, and filling-pieces at each end of the bolster, in the space between the beams.

2. A bolster for railway-cars, comprising a transverse member having an upper compression member with flanges and a lower tension member with flanges, said beams having their flanges placed side by side at the ends of the transverse member, and filling-pieces at each end of the bolster, in the space between the beams, and means for securing the beams and filling-pieces together.

3. A bolster for railway-cars, comprising a transverse member having an upper compression member with flanges, and a lower tension member with flanges, said beams having their flanges placed side by side at the ends of the transverse member, filling-pieces at each end of the bolster, in the space between the beams, and securing means passing through the flanges of the beams and through the filling-pieces.

4. A bolster for railway-cars, comprising upper and lower channel-beams, having their flanges overlapping at the ends of the bolster, and a filling-piece at each end of the bolster, in combination with a transversely-extending bolt at each end of the bolster, which bolt passes through the sides of both flanges and through the filling-piece.

5. A bolster for railway-cars, comprising upper and lower channel-beams, having their flanges placed side by side at the ends of the bolster, in combination with spring-coils, one near either end of the bolster, and wash provided with extensions which fit against the flanges of one of said channel-beams, and secured in position by bolts which pass through the extensions of the spring-coils and through the several flanges of the beams.

6. A bolster for railway-cars, comprising an upper channel-beam having its flanges downwardly disposed, a lower channel-beam having its flanges upwardly disposed, said beams being fitted together and having their flanges overlapping at the ends of the beams, and filling-pieces in the space between the beams at the ends of the bolster, in combination with means for securing the filling-pieces and the flanges of said beams together.

7. A bolster for railway-cars, comprising an upper channel-beam having its flanges downwardly disposed, a lower channel-beam having its flanges upwardly disposed, the said beams fitting together and having their flanges overlapping at the ends of the beams, and filling-pieces in the space between the beams at the ends of the bolster, in combination with a transversely-extending bolt passing through the filling-pieces and through all of the flanges of both beams.

8. A bolster for railway-cars, comprising an upper channel-beam having its flanges downwardly disposed, a lower channel-beam having its flanges upwardly disposed, said beams fitting together and having their flanges overlapping at the ends of the beams, and filling-pieces in the space between the beams at the ends of the bolster, in combination with securing means at each end of the bolster, comprising a transversely-extending bolt passing through the filling-pieces and through all the flanges of both beams, and a vertically-extended bolt passing through the webs of both beams and through the filling-piece.

698,877. APPARATUS FOR LEACHING TANBARK. GEORGE C. VANDER, Salem, Mass., assignor, by mesne assignments, to Virginia Machine Company, Boston, Mass., a Corporation of West Virginia. Filed Aug. 4, 1902. Serial No. 67,000. (No model.)

Claim.—1. In a leaching apparatus, a rotatable drum having a partition-wall forming a leaching-chamber and a liquor-chamber, and provided with a liquid-inlet for the leaching-chamber and with a plurality of separate outlets located within the leaching-chamber near the circumferential wall of the drum to move with the same and pass below the body of material being leached for the passage of extract or percolated liquor from said leaching-chamber into said liquor-chamber, strainers for said outlets affixed to the drum to pass below the said body of material, and means within the leaching-chamber to fill a portion of the material to be leached, substantially as described.

2. In a leaching apparatus, a rotatable drum having a partition-wall forming a leaching-chamber and a liquor-chamber, and provided with a liquid-inlet for said leaching-chamber, and with a plurality of separate outlets located within the leaching-chamber near the circumferential wall of the drum to move with the same and pass below the body of material being leached for the passage of extract or percolated liquor from said leaching-chamber into said liquor-chamber, strainers for said outlets affixed to the drum to pass below the said body of material, means within the leaching-chamber to fill a portion of the material to be leached, and a heating apparatus within said leaching-chamber, substantially as described.

3. In a leaching apparatus, a rotatable drum to contain the material to be leached, provided with a liquid-inlet, and with a liquid-outlet passage having side walls projecting inwardly from the inner circumference

of the drum and having a discharge-opening for the extract from said passage, and a strainer covering said outlet-passage, substantially as described.

4. In a leaching apparatus, a rotatable drum to contain the material to be leached, provided with its inner circumference with an outlet-passage for the extract liquor extended longitudinally of the drum and provided with an inlet for the extract from the drum and with a discharge-opening for the extract from said passage, a strainer covering the said inlet, and means within the drum for filling a portion of the material to be leached, substantially as described.

5. In a leaching apparatus, a rotatable drum provided with a partition-wall forming a leaching-chamber and a liquor-chamber, and having an outlet-passage for the extract from the leaching-chamber into the liquor-chamber, extended longitudinally of said drum within said leaching-chamber, a strainer for said outlet-passage, and a liquor-outlet for said liquor-chamber, substantially as described.

6. In a leaching apparatus, a rotatable drum having a partition-wall forming a leaching-chamber and a liquor-chamber, and provided with a liquid-inlet for the leaching-chamber, and with an outlet for the extract liquor into the liquor-chamber near the circumference of the drum, and a heating apparatus within the leaching-chamber attached to the drum to revolve therewith and comprising a steam-inlet pipe β^1 , a fitting β^2 , pipes β^3 , β^4 connected to said fitting and extended in substantially opposite directions toward the circumference of the drum, branch pipes β^5 , β^6 , β^7 , β^8 extended substantially at right angles near the opposite ends of the leaching-chamber, pipes β^9 , β^{10} extended longitudinally of the drum and connecting said branch pipes together, the pipe β^9 connecting the branch pipes β^5 , β^6 , to the pipe β^7 , and the outlet-pipe β^{10} connected to the said fitting, substantially as described.

7. In a leaching apparatus, a rotatable drum to contain the material to be leached, provided with a liquid-inlet and with a liquid-outlet passage for the extract having side walls projecting inwardly from the inner circumference of the drum and having a discharge-opening for the extract, and a strainer for said outlet-passage composed of a series of bars or disks, substantially as described.

8. In a leaching apparatus, a rotatable drum to contain the material to be leached, provided with a liquid-inlet and with a plurality of separate outlets for the extract liquor located within the said drum to pass below the mass or body of material being leached and provided with discharge-openings for the extract from said passages, strainers covering said outlets, and means within the drum to fill a portion of the material to be leached, substantially as described.

698,878. CENTRIFUGAL BRUSH-EXPPELLING MACHINE FOR BRUSHES. GEORGE A. VANDER, Lexington, Mass. Filed Feb. 12, 1902. Serial No. 67,700. (No model.)

Claim.—1. A centrifugal brush-expelling machine for brushes comprising a rotatable brush-carrier provided with brush-attaching means and operating means for said carrier.

2. A centrifugal brush-expelling machine for brushes comprising opposed brush-clamping members, a shaft to rotate the same, means to operate said shaft, and clamping means to press said clamping members one toward the other.

3. A centrifugal brush-expelling machine comprising a brush-carrying shaft and means to rotate it, a plurality of clamping members arranged on said shaft and adapted to hold between them a plurality of brushes, and a clamping device mounted on said shaft to press said clamping members one toward the other, to clamp between them said brushes.

4. A centrifugal brush-expelling machine comprising a plurality of clamping members adapted to receive and hold between them a plurality of brushes with means for individually clamping and releasing individual brushes, and means to rotate said clamping members.

5. A centrifugal brush-expelling machine comprising a plurality of clamping members adapted to receive and hold between them a plurality of brushes with means for moving said clamping members one bodily toward the other for simultaneously clamping and releasing said brushes, and means to rotate said clamping members.

word the other for simultaneously clamping and releasing said brushes, and means to rotate said clamping members.

6. In a machine of the class described a shaft, a table-like clamping member arranged thereon, an opposed segmental member, with means for moving the latter bodily toward the former.

7. In a machine of the class described a shaft, a table-like clamping member arranged thereon, an opposed segmental member, with means for moving the latter bodily toward the former, and means for moving the segments of said segmental member one toward and from the said table-like member one independent of another.

8. In a machine of the class described, a table-like clamping member, an opposed segmental member, the latter, means to move the latter and said segmental member toward said table-clamping member and means carried by the several arms of said spider member to act upon the segments of said segmental member.

9. A centrifugal brush-expelling machine comprising opposed members adapted to receive between them a brush or brushes to be acted upon, said members being provided with yielding flaps to engage the brush or brushes, and means to press said members one toward the other to clamp said brush or brushes between them.

10. A centrifugal brush-expelling machine comprising brush-rotating means and variable-speed driving mechanism therefor, whereby to vary the centrifugal action to accommodate the brush or brushes acted upon.

11. A centrifugal brush-expelling machine comprising a plurality of rotatable clamping members adapted to receive between them a brush or brushes to be acted upon, said members having raised clamping edges and yielding clamping-flaps adjacent said raised edges to engage the said brush or brushes, and means to move said members one toward the other.

698,879. SHEPPING CORD OR TAPE. EDWARD E. WARREN, Throsvick, Mich., assignor to the Warren Featherstone Company, Throsvick, Mich. Filed Dec. 2, 1902. Serial No. 34,430. (No model.)

Claim.—1. In a stiffening material, a strand comprising a series of quills denuded of their plumage, the plumage end of each quill of the series being inserted and cemented into the hollow end of the next succeeding quill.

2. In a stiffening material, a strand comprising a series of quills denuded of their plumage, the plumage end of each quill of the series being inserted and cemented into the hollow end of the next succeeding quill and a suitable wrapping-thread around the whole.

3. In a stiffening material, a strand comprising a series of quills denuded of their plumage, the plumage end of each quill of the series being inserted into the hollow end of the next succeeding quill and a suitable wrapping-thread around the whole.

4. In a stiffening material, a strand comprising a series of quills denuded of their plumage, the plumage end of each quill of the series being inserted into the hollow end of the next succeeding quill and a suitable wrapping-thread around the whole.

5. In a stiffening material, a strand comprising a series of quills denuded of their plumage, the plumage end of each quill of the series being inserted into the hollow end of the next succeeding quill of the series, the strands being retained together by a suitable wrapping-thread, as specified.

698,880. FEATHER SOUTER. EDWARD E. WARREN and ALBERT A. ANDERSON, Throsvick, Mich. Filed Feb. 20, 1903. Serial No. 42,041. (No model.)

Claim.—1. In a feather duster, the combination of a handle with an elongated head having a spiral rib thereon; a web of feathers, the bottom of which are woven in a fabric, the feathers being shorter at the inner end of the web, the web being wound on the spiral from the inner end out; and a retaining means to retain the web, as specified.

2. In a feather duster, the combination of handle with an elongated head having a spiral rib thereon; a web of feathers, the feathers being shorter at the inner end of the web, the web being wound on the spiral from the inner end out; and a retaining-wire wound onto the web to retain it in position, as specified.

688,881. FOUNTAIN-PEN. LEON R. WATKINS, Brooklyn, N. Y.; Frank D. Waterman executor of said Leon R. Waterman, deceased. Filed Feb. 1, 1904. Serial No. 577,678. (No model.)

Claim.—1. A feed-bar F provided with an air duct or channel D.
2. A feed-bar F provided with an air duct or channel D, and the automatic ink-valve or ink-opening O, in combination.
3. A feed-bar F of a fountain-pen, provided with an air duct or channel D and a capillary fissure or fissures S.
4. A feed-bar F of a fountain-pen, provided with an air duct or channel D, a capillary fissure, or fissures, S, and, in combination, an air-inlet opening O communicating with the air-duct D and located at its forward end.
5. The feed-bar of a fountain-pen, provided with an air duct or channel D, the sub-reservoir E, a capillary fissure, or fissures, S, and, in combination, an air-inlet opening O communicating with the air-duct D and located at its forward end.
6. The feed-bar of a fountain-pen, provided with an air duct or channel D, a sub-reservoir E, a capillary fissure, or fissures, S, and, in combination, an air-inlet opening O communicating with the air-duct D and located at its forward end, and made in and through the pen F.
7. The feed-bar of a fountain-pen, provided with an air duct or channel D, a sub-reservoir E, a capillary fissure, or fissures, S, and an air-inlet opening communicating with the air-duct D and located at its forward end, in combination with the main reservoir R.
8. The feed-bar of a fountain-pen, provided with an air duct or channel D, a sub-reservoir E, a capillary fissure or fissures S and an air-inlet opening O communicating with the air-duct, in combination with the main reservoir R, and with the conical nozzle N seated in a conical chamber in the forward end of the fountain or holder, forming an elastic conical joint between them.
9. The feed-bar of a fountain-pen, provided with an air duct or channel D, a capillary fissure, or fissures, S, a writing-pen P, and, in combination, an air-inlet opening O therein communicating with the air-duct D and located at its forward end.
10. A feed-bar F of a fountain-pen, provided with an air-duct D, a sub-reservoir E, a capillary fissure, or fissures S, a writing-pen P, and an air-inlet opening O communicating with the air-duct D, in and with which the ink conducted to the sub-reservoir E by the fissure, or fissures, S, can automatically be shut or open the ink-opening to the air by a valve-like action.
11. The feed-bar of a fountain-pen, provided with an air duct or channel communicating at its forward end with a sub-ink-reservoir located under the writing-pen and at the other end with the main ink-reservoir only at the lower side of the lower or forward end of the main ink-reservoir, with a capillary fissure, or fissures, connecting the two reservoirs, with an air-inlet opening communicating with the air-duct at its forward end and also with a secondary reservoir at its rear end.
12. The feed-bar of a fountain-pen, provided with an air duct or channel communicating at its forward end with an ink-reservoir located under the writing-pen and at the other end with the main ink-reservoir only at the lower side of its lower or forward end, with a capillary fissure, or fissures, connecting the two reservoirs, and also in combination with an air-inlet and ink-valve opening located and communicating with the air-duct at its forward end.

the lower side of the lower or forward end of the reservoir, with a capillary fissure, or fissures, connecting the two reservoirs, and also in combination with an air-inlet opening communicating with the air-duct and located at its forward end.

13. The feed-bar of a fountain-pen, provided with an air duct or channel communicating at its forward end with a sub-ink-reservoir located under the writing-pen and at the other end with the main ink-reservoir only at the lower side of the lower or forward end of the main reservoir, with a capillary fissure, or fissures, connecting the two reservoirs, with an air-inlet opening communicating with the air-duct at its forward end and also with a secondary reservoir at its rear end.

14. The feed-bar of a fountain-pen, provided with an air duct or channel communicating at its forward end with an ink-reservoir located under the writing-pen and at the other end with the main ink-reservoir only at the lower side of its lower or forward end, with a capillary fissure, or fissures, connecting the two reservoirs, and also in combination with an air-inlet and ink-valve opening located and communicating with the air-duct at its forward end.

15. The feed-bar of a fountain-pen, provided with an air duct or channel communicating at its forward end with a sub-reservoir located under the writing-pen and at the other end with the main ink-reservoir only at the lower side of its lower or forward end, with a capillary fissure, or fissures, connecting the two reservoirs, in combination with an air-inlet and ink-valve opening located and communicating with the air-duct at its forward end, and also with the sub-reservoir at its rear end.

16. The feed-bar of a fountain-pen, provided with an air duct or channel communicating at its forward end with a sub-ink-reservoir located under the writing-pen and at the other end with the main ink-reservoir only at the lower side of its lower or forward end, and also with a capillary fissure, or fissures, connecting the sub-ink-reservoir with the main ink-reservoir only at the lower side of the lower or forward end of the main reservoir.

17. The feed-bar of a fountain-pen, provided with an air duct or channel communicating at its forward end with a sub-ink-reservoir located under the writing-pen and at the other end with the main ink-reservoir only at the lower side of its lower or forward end, and also with a capillary fissure or fissures, connecting the sub-ink-reservoir with the main ink-reservoir only at the lower side of the lower or forward end of the main reservoir, in combination with the writing-pen provided with an air-inlet opening.

18. The feed-bar of a fountain-pen, provided with an air duct or channel communicating at its forward end with a sub-ink-reservoir located under the writing-pen and at the other end with the main ink-reservoir only at the lower side of its lower or forward end, with a capillary fissure, or fissures, connecting the sub-ink-reservoir with the main ink-reservoir at the lower side of its lower or forward end, and, also, in combination with an air-inlet and ink-valve opening located and communicating with the air-duct at its forward end and also with the sub-reservoir at its rear end.

19. In a feed-bar provided with a fissure or fissures for conducting the ink from the main reservoir to the writing-pen, an air-duct for conducting air to the reservoir, provided with means for increasing or diminishing the size of the air-duct at will.

20. In a feed-bar provided with a fissure or fissures for conducting the ink from the main reservoir to the writing-pen, an air-duct for conducting air to the reservoir, provided with means for increasing or diminishing the size of the air-duct at will, consisting of an adjustable device A.

21. In a feed-bar provided with a fissure or fissures for conducting the ink from the main reservoir to the writing-pen, an air-duct for conducting air to the reservoir, provided with means for increasing or diminishing the size of the air-duct at will, consisting of an adjustable device A for increasing and diminishing the area of the outlet-opening at the rear end of the feed-bar.

22. In a feed-bar provided with a fissure or fissures for conducting the ink from the main reservoir to the writing-pen, an air-duct for conducting air to the reservoir, provided with means for increasing or diminishing the size of the air-duct at will, consisting of an adjustable device A for increasing and diminishing the area of the outlet-opening at the rear end of the feed-bar, in combination with an air-inlet opening at the forward end of the air-duct.

23. The fountain or reservoir of a fountain-pen provided with a conical chamber at and near its open end, the mouth of which is thin and elastic, and the nozzle of a fountain-pen the rear end of which is externally conical in form and the extreme end of which is thin and elastic, making between these conical surfaces an elastic joint that is non-capillary.

24. The fountain or reservoir of a fountain-pen provided with a conical chamber at and near its open end, the mouth of which is thin and elastic, and the nozzle of a fountain-pen the rear end of which is externally conical in form and the extreme end of which is thin and elastic, making between these conical surfaces an elastic joint that is non-capillary at its outer end by contact.

25. The fountain or reservoir of a fountain-pen provided with a conical chamber at and near its open end, the mouth of which is thin and elastic, and the nozzle of a fountain-pen the rear end of which is externally conical in form and the extreme end of which is thin and elastic, making between these conical surfaces an elastic joint that is non-capillary at both ends by contact.

26. The fountain or reservoir of a fountain-pen provided with a conical chamber at and near its open end, the mouth of which is thin and elastic, and the nozzle of a fountain-pen the rear end of which is externally conical in form and the extreme end of which is thin and elastic, making between these conical surfaces an elastic joint that is non-capillary at both ends by contact, in combination with a feed-bar provided with an air duct or channel communicating at its forward end with an air-inlet opening and at its rear end with the main reservoir at the lower side of the lower or forward end of the same.

27. The fountain or reservoir of a fountain-pen provided with a conical chamber at and near its open end, the mouth of which is thin and elastic, and the nozzle of a fountain-pen the rear end of which is externally conical in form and the extreme end of which is thin and elastic, making between these conical surfaces an elastic joint that is non-capillary at both ends by contact, in combination with a feed-bar provided with an air duct or channel communicating at its forward end with an air-inlet opening and at its rear end with the main reservoir at the lower side of the lower or forward end of the same, and provided at its front end with an air-inlet opening accessible to the ink in the sub-reservoir for automatic valve action in opening and closing the air-duct.

28. The fountain or reservoir of a fountain-pen provided with a conical chamber at and near its open end, the mouth of which is thin and elastic, and the nozzle of a fountain-pen the rear end of which is externally conical in form and the extreme end of which is thin and elastic, making between these conical surfaces an elastic joint that is non-capillary at both ends by contact, in combination with a feed-bar provided with an air duct or channel communicating at its forward end with an air-inlet opening and at its rear end with the main reservoir at the lower side of the lower or forward end of the same and also with a capillary fissure or fissures connecting with the main reservoir and with the writing-pen.

29. A feed-bar of a fountain-pen provided with an air-duct and one or more capillary fissures fitting and filling the interior chamber in the rear end of the nozzle and expanding the same to form, by contact, an elastic non-capillary joint with the conical chamber in the front end of the reservoir in which it is seated.

30. In a fountain-pen and in combination, three elastic non-capillary joints, by contact, one between the cap and the fountain, another between the fountain and the nozzle, and still another between the nozzle and the feed-bar.

31. An elastic non-capillary joint between the rear end of the thin nozzle of a fountain-pen and the adjacent surface of the fountain, formed by elastic contact within the air of narrow threads.

32. In a fountain-pen, a nozzle in the form of three truncated female cones in combination with four surfaces in the form of male cones, forming three air and ink joints, one between the feed-bar and the nozzle, another between the nozzle and the fountain, and still another between the holder and the cap, substantially as shown and described.

33. A feed-bar provided with a surface in the form of a male cone inserted in a seat in the form of a truncated female cone provided in the rear end of the nozzle, in combination with a nozzle provided with a surface in the form of a truncated male cone inserted in a seat in the form of a truncated female cone provided in the forward end of the fountain, and also with a fountain provided on its front end with a truncated male cone inserted in a seat in the form of a truncated female cone provided in the open end of the cap.

34. A feed-bar provided with a surface in the form of a male cone inserted in a seat in the form of a truncated female cone provided in the rear end of the nozzle, in combination with a nozzle provided with a surface in the form of a truncated male cone inserted in a seat in the form of a truncated female cone provided in the forward end of the fountain, and also with a fountain provided on its front end with a truncated male cone inserted in a seat in the form of a truncated female cone provided in the open end of the cap, the open end of the cap being provided with a sheet truncated male cone on its exterior surface.

35. In the feed-bar of a fountain-pen, provided with an air-duct, a movable piston adjustable for increasing or diminishing the diameter of the air-duct and controlling the air movement into the reservoir.

36. In the feed-bar of a fountain-pen, provided with an air-duct, a movable piston arranged to diminish the size of the air-duct when moved toward the forward end of the feed-bar and to increase the size of the air-duct when moved to the opposite direction.

37. In a feed-bar of a fountain-pen, provided with an air-duct and one or more capillary fissures, a movable piston for increasing or diminishing the size of the air-duct and controlling the amount of air inflow.

38. A feed-bar of a fountain-pen in combination with an adjustable part A for increasing or diminishing the air-supply to the reservoir of a fountain-pen.

39. A non-capillary joint by contact, formed between a hollow elastic conical plug composed of hard rubber or other equivalent material and a conical cut in the top of a receptacle for fluids.

40. In a receptacle for fluids provided with an inwardly-tapering mouth related to an outwardly-tapering hollow plug or nozzle composed of hard rubber or other equivalent material, a non-capillary joint formed between the inner edge of the nozzle and a corresponding surface of the mouth of the receptacle.

41. In a receptacle for fluids provided with an inwardly-tapering mouth related to an outwardly-tapering hollow plug or nozzle composed of hard rubber or other equivalent material, a non-capillary joint formed between the inner edge of the nozzle and a corresponding surface of the mouth of the receptacle by the elastic resistance of the corresponding part of the inner member.

42. In the mouth of a receptacle for fluids, a conical chamber or nest and a conical hollow plug composed of hard rubber or other equivalent material forming a non-capillary joint between the lower end of the conical nest in the receptacle and the elastic inner end of the hollow plug.

688,882. SAFETY FOUNTAIN-PEN. LEON R. WATKINS, Brooklyn, N. Y.; Frank D. Waterman executor of said Leon R. Waterman, deceased. Filed May 14, 1904. Serial No. 580,681. (No model.)

Claim.—1. In a fountain-pen, a reservoir, a nozzle adapted to fit within the reservoir, and a cap adapted to fit either end of the nozzle and form a non-capillary joint therewith.

2. In a fountain-pen, a safety-cap provided with a chamber adapted to fit and form a non-capillary joint with the outer surface of either end of the nozzle, and a barrel or reservoir, in combination with the outside cap of the barrel or reservoir, in the chamber of which the safety-cap and the nozzle are receivable, and also in combination with the nozzle.

3. In a fountain-pen, a safety cap or cover provided with a chamber, and a barrel or reservoir, in combination with a nozzle, with either exposed end of which it may form a non-capillary joint, and also in combination with a reservoir or barrel cap, with the outer closed end and surface of which it is capable of forming a union or holding joint.

4. In a fountain-pen, a safety cap or cover provided with a chamber, and a barrel or reservoir, in combination with a nozzle, with either exposed end of which it may form a non-capillary joint, and also adapted, when removed and placed with its closed end inward, to form a non-capillary closure-joint within the mouth of the reservoir or barrel.

5. In a fountain-pen, a safety cap or cover in combination with a nozzle, with the rear end of which it forms a non-capillary joint, and also in combination with a barrel or reservoir, with which, and on its outer side, it also and at the same time forms a non-capillary joint-closure within the mouth of the barrel or reservoir.

6. In a fountain-pen, a safety reversible cap-plug receivable for use as a cap for the nozzle and a closing device for the fountain or holder, in combination with the nozzle and the fountain, the cap forming a non-capillary joint-closure within the chamber in the mouth of the fountain on and by the outside of its closed end, and with the nozzle on and by the inside surface of the chamber in the mouth of the cap.

7. In a fountain-pen, a hollow tapered reversible cap and plug the inner end of which is closed, in combination with a fountain and a nozzle, the plug forming on its outer surface a non-capillary closure-joint with the chamber-surface in the mouth of the fountain for closing the same, and also a non-capillary joint with the outside of the nozzle at either end of the same.

8. In a fountain-pen, a nozzle, a barrel and a safety-cap and hollow plug, in combination, the nozzle being externally conical at both ends, each end thereof being adapted to form a progressive non-capillary closure-joint with the mouth of the barrel, and also adapted to form a progressive non-capillary closure-joint at either end with the cap.

9. In a fountain-pen, a double-ended nozzle, a barrel and a cap or cover, in combination, the double-ended nozzle being adapted to form, at either end, a progressive non-capillary closure-joint with the open end and mouth of the barrel, and the cap or cover adapted to fit and form a progressive non-capillary closure-joint with and open either end of the double-ended nozzle, the cap also being adapted to form a progressive non-capillary closure-joint with the same chamber in the mouth of the barrel.

10. In a fountain-pen, a double-ended nozzle, a barrel and a cap or cover, in combination, the double-ended nozzle being adapted to form,

at either end, a progressive non-capillary closure-joint with the open end and mouth of the barrel, and the cap or cover adapted to fit and form a progressive non-capillary closure-joint with and upon either end of the double-ended nozzle, the cap also being adapted to form a progressive non-capillary closure-joint with the same chamber in the mouth of the barrel, and hermetically seal the mouth of the barrel.

11. In a fountain-pen, a reversible cap and a reversible externally-tapered hollow plug, an externally-tapered nozzle, and a barrel of a fountain-pen, in combination, the reversible cap and reversible hollow plug being adapted to form a progressive non-capillary closure-joint with the nozzle and also with the mouth of the barrel, and to hermetically seal and close the mouth of the barrel.

12. In a fountain-pen, a cap, a nozzle and a reservoir or barrel, in combination, the cap covering and protecting the writing-pen, hermetically closing the mouth of the reservoir or barrel, and forming a non-capillary and a union joint with the nozzle.

698,883. MACHINE FOR PREPARING QUILL SUBSTANCE.
WILLIAM WHELAN, Inventor, by Edgar A. Whelan, New York, N. Y. Filed Apr. 20, 1901. Serial No. 44,613. (No model.)

Claim.—1. In a machine of the class described, the combination of a suitable base; a bracket B thereon; a pair of feed-rolls supported by said bracket; a throat-piece E' through which the quills are introduced; a knife for splitting the quills supported back of said feed-rolls; guide-tubes F, F' to receive the halves of the split quill and turn the same with the pith downward; a pair of feed-rolls to carry the divided quill forward; an emery or other grinding wheel supported on a bracket F; a guide and shield over the top of the same with a removable steel pin G' for bringing the pith side of the divided quills into close contact with the grinding-wheel; a delivery-tube from the said shield; feed-rolls beyond the same; and slitting-disks intermeshing with each other to receive the quill beyond the feed-rolls and slit it into fiber, all coacting substantially as described, for the purpose specified.

2. In a machine of the class described, the combination of feed-rolls with a splitting-knife beyond the same; guides for turning the divided quill so that the pith side of each part will be in the same direction; feed-rolls for carrying the quill forward; a grinding-wheel with suitable guides in proximity thereto for removing the pith from said quills; a discharge-tube from the said grinding-wheel; slitting-disks beyond the same; and suitable feed-rolls for delivering the quill to the slitting-disks, coacting for the purpose specified.

3. In a machine of the class described, the combination of feed-rolls; a splitting-knife in proximity thereto; guides for receiving the halves of the quills, one of which at least, is spiral in formation to turn the parts of the quills so that the pith side will face in the same direction; feed-rolls for carrying the divided quills forward; a grinding-wheel beyond the last-named feed-rolls for grinding the pith from said quills coacting as specified.

4. The combination of a pair of feed-rolls; a block D in proximity to said feed-rolls having a throat across the same; a knife supported on

said block D; a cap-block D' with a throat d' therethrough to fit upon and retain the knife in position, coacting for the purpose specified.

5. The combination of the grinding-wheel; a shield or guide fitting loosely over the same and a projecting portion coming into close proximity to the wheel whereby quills coming in contact with the same will have the pith quickly removed without injury to the quill and the quill will be passed on over the same.

6. In a machine of the class described, the combination of a grinding-wheel F' on a suitable support; a guide or shield G over the same having a removable pin G' in close proximity to the wheel, for the purpose specified.

7. In a machine of the class described, the combination of parallel shafts; disks g, g, on said shafts intermeshing with each other; heavy disks g' to each side; and roller-guides for holding the disks g' in proper relation to cause the slitting-disks to be properly spaced without changing the same separately, coacting for the purpose specified.

8. In a machine of the class described, the combination of parallel shafts; disks g, g, on said shafts intermeshing with each other; heavy disks g' to each side; and guides for holding the disks g' in proper relation to cause the slitting-disks to be properly spaced without changing the same separately coacting for the purpose specified.

698,884. HINGE. GEORGE A. WHELAN, New York, N. Y. Filed Apr. 12, 1902. Serial No. 12,028. (No model.)

Claim.—1. In a hinge, the combination of a pair of knuckles, a cup or female track on one knuckle, a cone or male track on the other, said tracks being continuously inclined in one direction for more than a semi-circumference, and antifriction devices extending for more than a semi-circumference between said tracks.

2. In a hinge, the combination of an intermediate knuckle, a pair of outer knuckles, and inclined bearings between said intermediate knuckle and said outer knuckles, said bearings being inclined in opposite directions.

3. In a hinge, the combination of an intermediate knuckle, a pair of outer knuckles, and inclined antifriction-bearings between said intermediate knuckle and said outer knuckles, said bearings being inclined in opposite directions.

4. In a hinge, in combination, a knuckle having a shoulder, a bearing member having a cone projecting beyond said shoulder and a detachable stop on said cone adapted to hold said member in said knuckle.

5. In a hinge, in combination, a pair of leaves, a pair of knuckles on one of the leaves and an intermediate knuckle on the other, and a pair of bearings spirally inclined in opposite directions, between the inside faces of the pair of knuckles of one leaf and the adjacent faces of the intermediate knuckle of the other leaf, with a clearance between said pair of knuckles and said intermediate knuckle to allow the bearings to turn a suitable distance, one of the leaves being shorter than the other by an amount equal to the clearance in the bearings when the hinge is closed, whereby the two leaves will always be flush at one end when the hinge is either end up.

6. In a hinge, the combination of a pair of knuckles, an inclined bearing between said knuckles, and a pair of flaps on the adjacent ends

of said knuckles, said faces adapted to approach each other during the closing movement and to come together immediately before the closed position is reached, thereby forming a frictional stop.

7. In a hinge, the combination of a pair of knuckles, an inclined bearing between said knuckles, and a frictional stop between said knuckles and adapted to act during the closing movement of said hinge and immediately before the closed position is reached.

8. In a hinge, the combination of a pair of knuckles, a pair of bearing members therefor, one of said bearing members being detachable from its knuckle, and means for detachably attaching said members to each other.

9. In a hinge, the combination of a bearing member G having a shoulder g, a corresponding bearing member H having a core c' projecting beyond said shoulder g and having a circumferential groove c' on said core, and a spring-ring c' fitting said groove and holding said member H in said member G.

10. In a hinge, the combination of a pair of knuckles, ball tracks inclined continuously in one direction for more than a semicircumference at adjacent ends of said knuckles, and balls extending for more than a semicircumference between said tracks.

11. In a hinge, the combination of a pair of knuckles, bearings between said knuckles having tracks inclined continuously in one direction and making substantially a complete revolution, and antifriction devices between said tracks and extending over substantially the entire length thereof.

12. In a hinge, the combination of a knuckle, a bearing member at the end of said knuckle having a level face and a track member carried by said bearing member and having an inclined face.

13. In a hinge, the combination of a bearing member, a knuckle, and a corresponding projection and recess on said bearing member and knuckle, whereby said parts are detachable and attachable in a fixed relative position.

14. In a hinge, the combination of a hollow bearing member, a hollow knuckle, a corresponding rib and groove on said bearing member and knuckle, whereby said parts are attachable in a fixed relative position, and a pin passing through said parts whereby said parts are held together.

15. In a hinge, the combination of a pair of knuckles, a bearing member fixed in one of said knuckles, a second bearing member detachable from the other of said knuckles, and means for attaching said detachable bearing member to its knuckle.

16. In a hinge, the combination of a pair of knuckles, a bearing member fixed in one of said knuckles, a second bearing member detachable from the other of said knuckles, and means for attaching said detachable bearing member to its knuckle, so that said detachable bearing member will, when attached, be in a determined position relatively to said fixed bearing member.

17. In a hinge, the combination of a pair of knuckles, a bearing member fixed in one of said knuckles, its bearing-face being abruptly inclined at one point, a second bearing member detachable from the other of said knuckles and having a corresponding abrupt incline, and means for attaching said detachable bearing member to its knuckle so that said abrupt inclines will be approximately opposite each other in the closed position of said hinge.

18. In a hinge, the combination of a pair of knuckles, a bearing member fixed in one of said knuckles, a second bearing member detachable from the other of said knuckles, means for attaching said detachable member relatively to said first member and means for attaching said detachable member to its knuckle.

19. In a hinge, the combination of a pair of end knuckles, an intermediate knuckle, bearing members fixed in said end knuckles, corresponding bearing members detachable from said intermediate knuckle, means for attaching said detachable members relatively to their corresponding fixed members, and means for attaching said intermediate knuckle to said detachable members.

20. In a hinge, the combination of a pair of end knuckles B B', an intermediate knuckle A, fixed bearing members G and G' in said end knuckles, detachable bearing members E and E', means for placing said knuckle A and said members E and E' in a determined relative position, and a pin F passing through said intermediate knuckle and said detachable bearing members and holding the same together.

21. In a hinge, a pair of knuckles, a bearing between said knuckles consisting of a race for antifriction devices, the upper and lower tracks of said race being practically parallel and spirally inclined continuously for more than half of their circumference, and for the remaining distance consisting of an abrupt incline connecting the ends of the spiral, and antifriction devices in said race and extending for more than a semicircumference around the same.

22. In a hinge, a pair of leaves, knuckles on said leaves, and a pair of spirally-inclined bearings of equal pitch between adjacent pairs of

said knuckles, said bearings being inclined in the same direction and adapted to rotate reciprocally, one closing when the other opens, and vice versa, thereby taking up all lost motion.

23. In a hinge, the combination of a pair of knuckles, an inclined bearing between said knuckles, and corresponding recesses and projections c, p, on the adjacent faces of said knuckles, said projections adapted to rest in said recesses in the closed position and to resist the initial opening movement.

24. In a hinge, the combination of a bearing member having a plane face, an opposite inclined face, and a rib c on said plane face extending under the lowest point of said inclined face whereby said member is strengthened at its thinnest point.

25. In a hinge, the combination of a bearing member, a knuckle, a corresponding rib and groove on said bearing member and knuckle, and a leaf on said knuckle adapted to be attached to a door, said rib being advanced less than a quarter of a revolution beyond the line of said leaf.

26. In a hinge, the combination of a pair of spirally-inclined antifriction-bearings, the points at which said bearings are under load being on substantially opposite sides of said bearings, whereby substantially every point in the circumference of the axis of the hinge is under load at all times in one or the other of the bearings.

698,885. AUTOMATICALLY-OPERATING DOOR. JOHN H. WHITAKER, Inventor, Iowa. Filed Feb. 5, 1891. Serial No. 41,972. (No Model.)

Claim.—1. In an automatically-operating door, the combination of a door, a horizontal rail, means for suspending said door from the rail, an angular pivoted arm composed of three members, its upper member loosely connected with the rear of the door, its lower member provided with a weight, its third and shorter member extending laterally at right angles to the upper member, a vertical rod whose upper end is loosely connected with said shorter member, said rod extending through and some distance below the floor, a lever-arm supported and fulcrumed in a bearing underneath the floor, one end of said lever-arm loosely connected with the lower end of the vertical rod, a post whose lower end is connected with the other end of the lever-arm, a tread plate or button slightly raised above the floor and engaging the post for the purpose stated.

2. In an automatically-operating door, the combination of a horizontal rail, a door mounted thereon, guide-rods secured to the rear edge of the door, a roller between said guide-rods, an angular pivoted arm composed of three members, its lower member provided with a weight, its upper member connected with the roller, its third and shorter member extending at right angles to the upper member, a vertical rod whose upper end is loosely connected with said shorter member, said rod extending through and some distance below the floor, a lever-arm supported and fulcrumed in a bearing underneath the floor, one end of said lever-arm loosely connected with the lower end of the vertical rod, an upright post to whose lower end the other end of the lever-arm is loosely connected, a guide-plate having two downwardly-projecting notched ears, a tread-button adapted to move vertically in said guide-plate and provided with similar notched ears, a connecting-plate with four hook-shaped corners, each hook adapted to rest in the notched ears of the guide-plate and tread-button; the tread-button provided with a central socket on its under side to receive the upper end of the upright post for the purpose stated and substantially as described.

3. A tread-button having a central socket on its under side and provided at one edge with two downwardly-projecting notched ears, a guide-

2. The combination with the pawl-and-ratchet device, and the starting and reversing lever of a motor vehicle or car, of a lever mounted adjacent to the pawl and having means for controlling the position and move-

Clavin.—A pack of cards, having the letters of the alphabet severally marked on their backs, and the pictures or names of the Presidents severally marked corresponding in succession to the respective letters of the alphabet on their faces, substantially as specified.

It is a sliding-iron bracket, a casing having tool-receiving openings formed therein, a draft-pipe leading from the casing, and a tool-holder supported by the draft-pipe, said tool-holder comprising a ring member and a collar, said ring member being connected with the draft-pipe and with the casing and securing the upper end of the draft-pipe against displacement.

3. In a soldering-iron heater, a casing having fuel-receiving openings formed therein, a draft-pipe leading from the casing, and a fuel-burner, said burner comprising a nozzle supported solely by the draft-pipe and a ring member connected with the draft-pipe and with the casing.

698,895. CONTINUOUS-COMBUSTION THERMIST. MICHAEL B. B. MINNEAPOLIS, MINN. Filed Oct. 6, 1903. Serial No. 32,320. (No model.)

Claim.—1. The combination with a rotatable member carrying means for transmitting power, of a second reversely-rotatable member freely rotatable with reference thereto, a pump for supplying motive fluid carried and actuated by said second member and serving as a sole base of reaction therefor, each member having alternately-arranged plates carrying propelling-blades, the plates of the one member being interposed between those of the other.

2. In a rotary engine, the combination with a fixed hollow spindle, of a pair of reversely-rotatable members mounted on said spindle, the one embracing the other, said members having alternately-arranged propelling-plates with cooperating propelling-blades, a pair of pumps having pistons working within the hub of the inner member, means for sliding said pistons on said spindle under the rotary movement of the said inner rotary member, means for supplying motive fluid to the ends of said spindle, and from thence to the pumps, and means for transmitting power from the outer rotary member, substantially as described.

698,896. LIFTING-JACK OR ELEVATOR. CHARLES E. BROWN. St. Louis, Mo. Filed Nov. 10, 1901. Serial No. 22,500. (No model.)

Claim.—1. A lifting-truck comprising a suitable base mounted on wheels; a frame extending upwardly from the base; a platform mounted to move up and down in said frame; a gear-rack carried by said platform for moving the same; a ratchet-rack carried by said platform for supporting the same; a shaft mounted in said frame; a gear on said shaft and operating said rack; a ratchet and lever for operating said gear; and a pawl to engage said ratchet-rack and hold it from sliding downwardly, substantially as specified.

2. A lifting-truck comprising a suitable base; a frame extending upwardly from the base; a platform to move up and down in said frame; rollers forming the floor of said platform; a gear-rack carried by said platform; a ratchet-rack carried by said platform; a shaft mounted in said frame; a gear on said shaft for operating said rack; a ratchet and lever for operating said gear; and a pawl engaging said ratchet-rack to hold it from sliding downwardly, substantially as specified.

3. A lifting-truck comprising a suitable base; a frame extending upwardly from the base; a platform mounted to move up and down in said frame; a gear-rack carried by said platform; a shaft mounted in said frame; a gear on said shaft for operating said rack; a ratchet and lever for operating said gear; and a pawl to engage said ratchet-rack and hold the rack from sliding downwardly; and means of releasing said pawl as required to lower the platform, substantially as specified.

698,897. WITHDRAWN.

698,898. REFRIGERATOR. WILLIAM BROWN, and JULIA BROWN, Philadelphia, Pa. Filed Nov. 7, 1901. Serial No. 21,302. (No model.)

Claim.—1. A submerger adapted to supply at will either a single vapor or a mixture of vapors from different wells and provided with a central air-tube which is also the main support, a series of submerging-balls, a series of branch air-tubes which serve as their means of suspension and are provided with shut-off valves and a series of cold radial rods or bars extending from the said central tube to the individual submerging-balls substantially as set forth.

2. A submerger provided with a series of independent submerging-balls, a series of rigid cold suspending-tubes bending down in them to the supply of compressed air and a central air-tube extending continuously up through the submerging-tubes to the said suspending-tubes, the said tubes extending to below and support the said balls and permitting one or more of them to be brought into action at the same time as preferred, substantially as set forth.

3. A submerger provided with a series of isolated submerging-balls, means of supplying air to them individually from above and said radial rods or bars extending to a central support, the said means of supplying air, also extending to support and brace the said balls, substantially as set forth.

698,899. APPARATUS FOR THE MANUFACTURE OF KNITTING CARPETS. FERNAND BOUTER, Paris, France. Filed July 27, 1900. Serial No. 22,004. (No model.)

Claim.—1. In a loom for the mechanical manufacture of knit-stitch carpets, the combination of needles for the passage of the pile-threads of the carpet between the threads forming the ground-warps, said needles having two points, clips by means of which said needles are successively conducted from the front toward the back and from the back toward the front through the warps, carriages upon which said clips are mounted, a fixed frame over which said carriages move, the frame which carries the ground warp-threads being moved successively the space of two threads or two intervals according to the path which the needle is to take with relation to the fabric.

2. In a knit-stitch loom for the mechanical manufacture of knit-stitch carpets, a pair of carriages, a series of spring-closed needle-clips supported on each carriage, said clips having tails for opening them, a longitudinal bar placed above each clip-supporting carriage and pivoted at the two ends of the carriages and adapted to press on the tails of all the clips for releasing the needles, and means for covering this movement for the two carriages, the gripping operation of one being effected while the releasing operation of the other is taking place and at the moment when the needles are in the ground-warps.

3. In a knit-stitch loom for the mechanical manufacture of knit-stitch carpets, a pair of carriages, a series of spring-closed needle-clips supported on each carriage, a longitudinal bar adapted to open the clips of each carriage, a lever pivoted at an intermediate point, each of the ends of the said lever engaging one of the bars which actuate the clips, and pedals for swinging said lever in opposite directions, whereby when said carriages approach one another the needles may be gripped by one and released by the other.

4. In a loom for the mechanical manufacture of knit-stitch carpets the combination of needles for the passage of the pile-threads of the carpet between the threads forming the ground-warps, said needles having two points, clips by means of which said needles are successively conducted from the front toward the back and from the back toward the front through the warps, carriages upon which said clips are mounted, a fixed frame over which said carriages move, the frame which carries the ground warp-threads being moved successively the space of two threads or two intervals according to the path which the needle is to take with relation to the fabric, a bar having two rows of closely-approximated holes, the said bar serving to guide the needles, and means whereby it may be caused to rise or descend at intervals between two rows of holes in order to prevent the needles in their return movement to the middle of the two warp-threads forming the stitch, from placing the length of pile-thread already engaged between the two ground warp-threads.

5. In a loom for the mechanical manufacture of knit-stitch carpets, the combination of needles for the passage of the pile-threads of the carpet between the threads forming the ground-warps, said needles having two points, clips by means of which said needles are successively conducted from the front toward the back and from the back toward the front through the warps, carriages upon which said clips are mounted, a fixed frame over which said carriages move, the frame which carries the ground warp-threads being moved successively the space of two threads or two intervals according to the path which the needle is to take with relation to the fabric, a bar having two rows of closely-approximated holes, the said bar serving to guide the needles, means whereby it may be caused to rise or descend at intervals between two rows of holes in order to prevent the needles in their return movement to the middle of the two warp-threads forming the stitch, from placing the length of pile-thread already engaged between the two ground warp-threads, a counter-shaft guiding the pile warp-threads below the passage of the needles, and means whereby it may be caused to rotate, together with said perforated bar, when the leading of the stitch upon the face of the fabric takes place.

6. In a loom for the mechanical manufacture of knit-stitch carpets, the combination of needles for the passage of the pile-threads of the carpet between the threads forming the ground-warps, said needles having two points, clips by means of which said needles are successively conducted from the front toward the back and from the back toward the front through the warps, carriages upon which said clips are mounted, a fixed frame over which said carriages move, the frame which carries the ground warp-threads being moved successively the space of two threads or two intervals according to the path which the needle is to take with relation to the fabric, and a vertically-moving bar, an endless chain for operating said bar, gearing for driving said chain, and a hand-wheel controlling said gearing.

7. In a loom for the mechanical manufacture of knit-stitch carpets, the combination of needles for the passage of the pile-threads of the carpet between the threads forming the ground-warps, said needles having two points, clips by means of which said needles are successively conducted from the front toward the back and from the back toward the front through the warps, carriages upon which said clips are mounted, a fixed frame over which said carriages move, the frame which carries the ground warp-threads being moved successively the space of two threads or two intervals according to the path which the needle is to take with relation to the fabric, and a mechanism designed to slightly stretch the ground-warps on the opening of the shed for the purpose of facilitating the passage of the needles.

8. In a loom for the mechanical manufacture of knit-stitch carpets, the combination of needles for the passage of the pile-threads of the carpet between the threads forming the ground-warps, said needles having two points, clips by means of which said needles are successively conducted from the front toward the back and from the back toward the front through the warps, carriages upon which said clips are mounted, a fixed frame over which said carriages move, the frame which carries the ground warp-threads being moved successively the space of two threads or two intervals according to the path which the needle is to take with relation to the fabric, and a clip for lifting the needle-threads for the purpose of giving a slight tension to the said threads by lifting the warps above the needles when the second length of yarn passes through the middle of the stitch.

9. In a loom for the mechanical manufacture of knit-stitch carpets, the combination of needles for the passage of the pile-threads of the carpet between the threads forming the ground-warps, said needles having two points, clips by means of which said needles are successively conducted from the front toward the back and from the back toward the front through the warps, carriages upon which said clips are mounted, a fixed frame over which said carriages move, the frame which carries the ground warp-threads being moved successively the space of two threads or two intervals according to the path which the needle is to take with relation to the fabric, and a safety-bar carried by the front carriage for bringing down the needle-threads below the needles for the purpose of preventing the latter from leaving the clips when tension is placed upon the stitch formed.

10. In a loom for the mechanical manufacture of knit-stitch carpets, the combination of needles for the passage of the pile-threads of the carpet between the threads forming the ground-warps, said needles having two points, clips by means of which said needles are successively conducted from the front toward the back and from the back toward the front through the warps, carriages upon which said clips are mounted, a fixed frame over which said carriages move, the frame which carries the ground warp-threads being moved successively the space of two threads or two intervals according to the path which the needle is to take with relation to the fabric, a beam-carrying frame having a lateral movement, a jointed lever, and a cam guiding the frame.

11. In a loom for the mechanical manufacture of knit-stitch carpets,

the combination of needles for the passage of the pile-threads of the cap between the threads forming the ground-warp, said needles having two points, clips by means of which said needles are successively conducted from the front toward the back and from the back toward the front through the warps, carriages upon which said clips are mounted, a fixed frame over which said carriages move, the frame which carries the ground warp-threads being moved successively the space of two threads or two intervals according to the path which the needle is to take with relation to the fabric, a bar having two rows of exactly-spaced holes, the said bar serving to guide the needles, means whereby it may be caused to rise or descend at intervals between two rows of holes in order to prevent the needles in their return movement to the middle of the two warp-threads forming the stitch, from piercing the length of pile-thread already engaged between the two ground warp-threads, a counter-shaft guiding the pile warp-threads below the passage of the needles, means whereby it may be caused to rotate, together with said perforated bar, when the locking of the stitch upon the face of the fabric takes place, a main shaft, a ratchet and pawl actuated by the workman for operating said shaft at every operation or stage in the formation of the stitch, and cam on said shaft arranged to actuate said perforated bar and counter-shaft.

698,900. CLAMP FOR ROCK-DRILLS. FRANK E. BROWN, Unga, Alaska. Filed July 13, 1901. Serial No. 64,754. (No model.)

Claim.—1. In a clamp for rock-drills, the combination with a stand or support having a frame-central pivot, of a clamp comprising two oppositely-disposed conical-jaws adapted to embrace the barrel of the drill-bit, one of said jaws being provided with a substantially U-shaped base and the other jaw being provided with a base arranged to slide between the sides of said U-shaped base, each of said bases on their inner edges being provided with arc-shaped dovetailed grooves, the said bases embracing the pivot on the stand, and means carried by the ends of the jaws for adjustably drawing the latter and said bases together, substantially as described.

2. In a clamp for rock-drills, the combination with a stand or support having a laterally-projecting pivot, of a clamp comprising two oppositely-disposed conical-jaws adapted to embrace the barrel of the drill, one of said jaws being provided with a substantially U-shaped base and the other jaw being provided with a base arranged to slide between the sides of said U-shaped base, each of said bases on their inner edges being shaped to correspond to the shape of the said pivot and to embrace and clamp the latter, a screw pivoted at one end to one end of one of said jaws and loosely passing through the corresponding end of the other jaw, and a nut screwed over the end of said screw for drawing the jaws and bases together, substantially as described.

3. In a clamp for rock-drills, the combination with a stand or support having a frame-central pivot, of a clamp comprising two oppositely-disposed conical-jaws adapted to embrace the barrel of the drill-bit, one of said jaws being provided with a substantially U-shaped base and the other jaw being provided with a base arranged to slide between the sides of said U-shaped base, each of said bases upon their inner edges being provided with arc-shaped dovetailed grooves, a screw pivoted at one end to one end of one of said jaws and loosely passing through the corresponding end of the other jaw, and a nut screwed over the end of said screw for drawing the jaws and bases together, said bases embracing the pivot on the stand, substantially as described and for the purpose specified.

698,901. PHOTOGRAPHIC CAMERA. FRANK A. BROWNELL, Rochester, N. Y., assignor to the Eastman Kodak Company, Rochester, N. Y., a Corporation of New York. Filed July 26, 1901. Serial No. 64,755. (No model.)

Claim.—1. In a camera, the combination with the casing having film-chambers at opposite ends, and a central chamber between them, having the way at the bottom, of a door for closing the central chamber and hinged near one of the film-chambers, and on a center parallel with the axis thereof and the hinged supporting-leg upon the outer side of the door.

2. In a camera, the combination with the casing having the film-chambers at top and bottom, and a central chamber between them, having a way-plate at the bottom, of a door hinged at the lower edge of the central chamber on a center parallel with the axis of the film-chamber and having a way thereon, two adjustable legs or supports mounted on the door one movable from the lower face thereof, and the other from one of the sides, a lens-support movable on the ways, and a bellows connected thereto.

3. In a camera, the combination with the casing having the film-chambers at top and bottom and a central chamber between them having a way at the bottom, of a door hinged at the lower edge of the central chamber on a center parallel with the axis of the film-chamber and having a way thereon, the supporting-leg pivoted upon the door and extendible beneath the same, the supporting-leg sliding upon the door and extendible laterally thereof, the lens-support movable on the ways, and the bellows connected thereto.

4. In a camera, the combination with the casing having the film-chambers at top and bottom, and a central chamber between them having a way at the bottom, of a door hinged to the lower edge of the central chamber on a line parallel with that of the film-chamber having a way thereon, the supporting-leg near the outer portion of the door sliding laterally thereof, and movable below the edge when the camera is on its side, and a lens-support movable upon the ways, and a bellows connected thereto.

5. In a camera, the combination with the casing having the film-chambers at top and bottom, and a central chamber between them having a way at the bottom, of a door hinged to the lower edge of the central chamber on an axis parallel with that of the film-chamber having the way thereon, the folding supporting-leg hinged to the outer side of the door, and means for holding it extended at an angle to the door or parallel therewith, a lens-support movable on the ways, and a bellows connected thereto.

6. In a camera, the combination with the casing having the film-chambers at top and bottom, and the central chamber between them having the track-plate therein, the hinged door adapted to close the central chamber having the track-plate thereon, the lens-support movable on the track-plate, and the bellows connected thereto, said support and bellows being adapted to fold within the central chamber, of the plates at the top of the camera-casing having the loops, the handle attached to the loops, and speed-controlling devices on the plates and extending into the upper film-chamber.

7. In a camera, the combination with the casing having the central chamber provided with the way at the bottom, of the door hinged to the lower edge of the chamber and movable on the hinge to cover the chamber, ways on the door, the lens-support movable on the ways, and the bellows connected thereto the supporting-legs pivoted to the door having the longitudinal slots and provided with recesses at the ends of said slots, and the springs secured to the hinge, and the pins in the casing operating in the slots and engaged by the springs on the hinge to lock the door in extended position.

8. In a camera, the combination with the casing having the central chamber, the way therein, the door hinged to the edge of the chamber having the way thereon, and the lens-support movable on the ways, of the notched supporting-leg sliding transversely of the door near the outer

portion thereof, and the spring engaging said notches to hold the legs extended.

698,902. CUSHION. CHAMBERLAIN BROS. & CO. Ltd., London, W. Filed Dec. 8, 1901. Serial No. 64,756. (No model.)

Claim.—1. A self-contained cushion made of sections composed of a single material and provided with cable-receiving grooves and end and side flanges, and each section being a complete integral body having sufficient superficial area, strength and weight to be self-supporting and to retain alignment of the sections independent of any external device; substantially as specified.

2. A cushion-section made of concrete, having its ends cut away at diagonal corners and provided with semicircular grooves in its top and bottom faces, substantially as specified.

3. A cushion-section made of concrete and having on its one end and side, flanges 2, and upon one of its faces semicircular grooves 3, in combination with two additional sections also made of concrete and having a transverse effect in each end, and semicircular grooves upon opposite sides; substantially as specified.

4. A cushion-section made of concrete and having on its one end and side, flanges 2, and upon one of its faces semicircular grooves 3, in combination with two additional sections also made of concrete and having a transverse effect in each end, and semicircular grooves upon opposite sides of said additional sections, said additional sections being also provided with marginal recesses 7 in which said side flanges 2 are located, there being a space for contact between said side flanges and the walls of the said recesses, substantially as specified.

698,903. RUBBER MACHINERY AND STARTING MACHINE. JOHN F. GARR, St. Louis, Mo. Filed Dec. 4, 1901. Serial No. 64,757. (No model.)

Claim.—1. A starting-machine having a main frame, a series of projecting hinged shafts, automatically-released front bearings for said shafts, and means for folding said shafts against the said frame, substantially as specified.

2. A starting-machine, consisting of a frame, a plurality of shafts formed by side bearings, said side bearings being hinged to the frame, and means for folding the same, substantially as specified.

3. A starting-machine, consisting of a suitable frame, a plurality of side bearings hinged to and projecting from said frame, means for folding said bearings, front bearings carried by the side bearings, a locking mechanism carried by the side bearings for holding the front bearings, and means for automatically releasing the same, substantially as specified.

4. A device of the class described, comprising a series of frames forming shafts, said frames padded and hinged to a frame, means for locking the frames in a rigid position, a locking mechanism and front bearings carried by the frames, means for releasing the front bearings, and means for releasing the frames for moving or folding the same, substantially as specified.

5. A starting-machine of the class described, consisting of a frame mounted upon tracks, a plurality of frames forming shafts pivotally connected to and projecting from said frame, a locking mechanism mounted in the frame for locking the shafts, front bearings carried by the shafts, a locking mechanism for retaining the front bearings across the shafts, and means for simultaneously releasing all the front bearings, substantially as specified.

698,904. BUSHING-PAD. HENRY CHAMBERLAIN, Brooklyn, N. Y. Filed May 2, 1901. Serial No. 64,758. (No model.)

Claim.—1. A pad for bushings, comprising a central body portion adapted to fill the shoe, a top portion of leather which overlaps the central body portion of the pad and the shoe, the body portion of the pad being also provided centrally with a cushion which is covered by the top portion of the pad, said top portion of the pad and said body portion and the central cushion being perforated, substantially as shown and described.

2. A bushing-pad composed of rubber or similar material and adapted to fill the shoe and provided with a top portion of leather which overlaps the pad and the shoe, the body portion of the pad being also provided with detachable self-holders and collars, substantially as shown and described.

3. A bushing-pad comprising a body portion which is adapted to fill the shoe, a top portion which overlaps the body portion and the shoe, a central cushion which is also covered by the top portion, said body portion being provided in the top thereof with a groove around said cushion, and said top and body portions with perforations which communicate with said groove, substantially as shown and described.

4. A bushing-pad comprising a body portion which is adapted to fill the shoe, a top portion which overlaps the body portion and the shoe, a central cushion which is also covered by the top portion, said body portion being provided in the top thereof with a groove around said cushion, and said top and body portions with perforations which communicate with said groove, the said pad being also provided just within the shoe with perforations substantially as shown and described.

5. A bushing-pad comprising a body portion which is adapted to fill the shoe, a top portion which overlaps the body portion and the shoe, a central cushion which is also covered by the top portion, said body portion being provided in the top thereof with a groove around said cushion, and said top and body portions with perforations which communicate with said groove, the said pad being also provided just within the shoe with perforations, and the top portion of the shoe and the central cushion being also perforated, substantially as shown and described.

6. A bushing-pad provided with elastic and detachable self-holders on which are on thereinto, and collars detachably secured in said holders, substantially as shown and described.

7. A bushing-pad composed of top and bottom portions, the bottom portion being provided with a groove in the top thereof and both of said portions being provided with perforations or openings which communicate with said groove, substantially as shown and described.

698,905. VALVE FOR FRICTIONLESS MACHINERY. EDWARD CLARK, Chicago, Ill. Filed July 12, 1901. Serial No. 64,759. (No model.)

Claim.—1. A valve for pneumatic medical instruments comprising a button of non-yielding material having a centrally-arranged opening therethrough, a stem of less diameter than the smallest diameter of said opening passing loosely through the latter, a valve-seat of yielding material on one face of the button, and means acting upon opposite sides of the valve for preventing any appreciable longitudinal movement thereof relatively to the stem, the arrangement being such that the valve may have a universal angular movement on the stem, for the purpose specified.

2. A valve for pneumatic medical instruments comprising a centrally-apertured button of non-yielding material, a stem of less diameter than said aperture passing freely therethrough, a valve-seat of yielding material on one face of the button, and a flexible connection between said valve-seat and button, the arrangement being such that the valve will have a universal angular movement on the stem.

3. A valve for pneumatic medical instruments comprising a centrally-apertured button of non-yielding material, a stem of less diameter than said aperture passing freely therethrough, a valve-seat of yielding material on one face of the button, and a flexible cover including the valve-seat and having a connection with the button.

4. A valve for pneumatic medical instruments comprising a stem, a valve-body loosely mounted on the stem and universally movable angularly relatively to the stem, and means carried by the stem and acting upon opposite faces of the valve to prevent the latter from moving longitudinally on the stem, for the purpose specified.

5. A valve for pneumatic medical instruments comprising a piston, a valve-body mounted loosely on the stem and universally movable angularly relatively to the stem, a flexible valve-seat disposed on one face of the valve-body, and means carried by the stem and acting upon opposite sides of the valve-body for preventing the latter from moving longitudinally on the stem, substantially as specified.

6. In a pneumatic medical instrument, the combination with a primary pneumatic valve movable wall is flexibly attached to its support, of a valve-stem secured to said movable wall, a valve loosely mounted on the stem and universally movable angularly relatively to the stem, and means carried by the stem acting upon opposite sides of the valve to prevent the latter from moving longitudinally on the stem, the arrangement being such that the valve is free to rock on its stem when it engages the valve-seat, without sliding over whatever point of its face first strikes the seat, whereby the entire face of the valve is squarely seated.

7. A valve for pneumatic medical instruments comprising a button of non-yielding material provided centrally on one side with a counter-disk and centrally perforated, a screw of less diameter than said perforation passing through the latter, the head of the screw being seated in the said counter-disk, means for yieldingly connecting the button to the screw so that it will be capable of moving freely thereon in an angular direction relatively to the stem, and means for preventing the button from moving longitudinally on the stem, substantially as described.

8. A valve for pneumatic medical instruments, comprising a valve-stem, a button mounted on the stem and freely movable in an angular direction relatively thereto, a yielding disk disposed on the face of the button, and a flexible strip extending over the face of the disk and attached to the button for holding the disk in place, substantially as described.

9. A valve for pneumatic medical instruments, comprising a valve-stem, a button mounted on the stem and freely movable in an angular direction relatively thereto, a yielding disk disposed on the face of the button, and a flexible cover extending over the face of the disk and the sides of the button, and a washer secured upon the screw against said cover, substantially as described.

10. A valve for pneumatic medical instruments, comprising a valve-stem, a button mounted on the stem and freely movable in an angular direction relatively thereto, a yielding disk disposed on the face of the button, and a flexible cover extending over the face of the disk and the sides of the button, and a washer secured upon the screw against said cover, substantially as described.

11. A valve for pneumatic medical instruments, comprising an adjusting-screw, a rigid button provided centrally with a perforation larger than the screw through which the latter passes whereby the button is freely movable on the screw in an angular direction relatively to the latter, a yielding disk disposed on the face of the button, a flexible cover extending over the face and sides of the disk and attached to the sides of the button, and a washer secured upon the screw against said cover, substantially as described.

12. A valve for pneumatic medical instruments, comprising an adjusting-screw, a wooden button provided centrally with a perforation larger than the screw through which the latter passes whereby the button is freely movable on the screw in an angular direction relatively to the latter, a yielding disk disposed on the face of the button, a flexible cover extending over the face and sides of the disk and attached to the sides of the button, and a relatively small washer secured upon the screw against the leather cover, substantially as described.

13. A valve for pneumatic medical instruments, comprising a cylindrical wooden button provided centrally on one side with a counter-disk and centrally perforated, a disk disposed on the other side of the button, a thin leather cover extending over the face and sides of the disk and connected to the sides of the button, a screw of less diameter than the said perforation and passing through the latter, the disk and the cover, whereby the valve is freely movable on the screw in an angular direction relatively to the latter, and a relatively small leather washer secured upon the screw against the said cover, the head of the screw being seated in the said counter-disk, substantially as described.

14. A valve for pneumatic medical instruments, comprising a valve-stem, a button yieldingly connected to the stem and freely movable in an angular direction relatively thereto, said button being cushioned on its opposite faces, substantially as described.

698,906. NON-DEPRESSIBLE BOTTLE. FRANK H. COTTER, Boston, Pa. Filed Jan. 11, 1902. Serial No. 95,857. (No model.)

Claim.—1. In combination with a bottle provided with a shoulder in its neck and two oppositely-arranged grooves or channels in said shoulder, of a stopper fitting therein and having a spring-actuated pivoted lever or bar upon its lower edge to engage the shoulder.

2. In combination with a bottle having an inclined projection in the neck thereof and two oppositely-arranged grooves or channels in said projection, of a stopper thereto consisting of an inverted truncated conical body adapted to fit in the inclined projection of the neck, and a spring-actuated pivoted bar or lock carried upon the lower end of the body and adapted to engage the under side of the inclined projection.

3. In combination with a bottle having a neck provided with an inclined projection and two oppositely-arranged channels or grooves, of a stopper comprising a truncated conical body, a pair of oppositely-arranged legs formed integral with the body and adapted to fit in the grooves of the neck, and a spring-actuated lock mounted upon the lower end of the body adapted to hold the body in place in the neck.

4. In combination with a bottle having an inclined projection provided with two oppositely-arranged channels or grooves, of a stopper comprising a truncated conical body, two oppositely-arranged wings or legs formed integral with the body and adapted to fit in the channels of the neck, a bar or arm pivoted to the lower end of the body adapted to be in line with the legs when the stopper is being inserted, and a spring adapted to operate said lock to throw it out of line with the legs when the stopper is inserted.

698,907. BOTTLE-CLOSURE. JAMES BAKER, Aberdeen, Scotland. Filed June 25, 1901. Serial No. 95,904. (No model.)

Claim.—1. A bottle closure or stopper, having a cap-plate provided on the inside with a hollow central plug provided adjacent to the bottom with an annular groove topped by an outwardly-extending annular flange,

a washer of elastic material located in the annular groove, and means co-acting with the outwardly-extending annular flange for locking the stopper in position in the bottle, substantially as shown and described.

2. A bottle closure or stopper, having a cap-plate provided on the inside with a hollow central plug provided adjacent to the bottom with an annular groove topped by an outwardly-extending annular flange, a washer of elastic material located in the annular groove, a covering of flexible protective material for the washer, and means co-acting with the outwardly-extending annular flange for locking the stopper in position in the bottle, substantially as shown and described.

3. In a bottle closure, the combination with a bottle provided adjacent to the neck-cribs with two legs extending from the bottle-neck on opposite sides provided with square bases and an oppositely-arranged sloping surface curving gradually toward and merging into the bottle-neck at the upper end, and perforations having formed in and through the side of the bottle-neck adjacent to the legs, of a stopper provided at the inner end with an annular ring of elastic packing material, a flange located above the ring of elastic packing material, and a spring-hall with inwardly-turned ends, which ends are adapted to pass through the perforations and into the neck-cribs above the flange of the stopper so as to hold the same in place, substantially as shown and described.

4. A bottle closure or stopper having an outer top cap-plate adapted to shut upon the outer end of the bottle-cribs, an annular flange extending inward from the cap-plate and adapted to fit snugly into the bottle-cribs, a central plug extending forward from the cap having an annular groove at the inner end, a ring of elastic packing material carried by the groove, and means for securing the stopper in place in the bottle, substantially as shown and described.

698,908. CLOTH-CUTTING MACHINE. FRANK BAKER, Boston, Mass. Filed Sept. 7, 1901. Serial No. 94,642. (No model.)

Claim.—In a cloth-cutting machine a cylinder, a piston, a cross-head attached to said piston, said cross-head being provided with means for connecting a knife thereto to reciprocate therewith, said cross-head being

provided with a slot, in combination with a rotary gear carrying a cam-pin adapted to reciprocate in said slot, and said casing being provided with a bearing for a rotary shaft, in combination with means connecting said rotary shaft with said gear whereby said machine may be rendered convertible from a rotary cutting-machine to a reciprocating cutting-machine, as described.

698,909. AUTOMOBILE. GEORGE F. DUNN, St. Louis, Mo., assignor of one-half to St. Louis Motor Carriage Co., St. Louis, Mo. Filed Oct. 10, 1900. Serial No. 23,614. (No model.)

Claim.—1. In a motor-vehicle, a plurality of springs; hinge-blocks fixed to the upper sides of the springs; hinge-brackets connected to the hinge-blocks; a frame or bed connected to the hinge-brackets; bearing-blocks connected to the lower sides of the springs; axle rotatably mounted in said bearing-blocks; rockers connecting the forward bearing-blocks to the corresponding rear bearing-blocks, said rockers being pivotally mounted; hinge-collars mounted upon the rear axle; a crank-shaft mounted upon the frame; a crank-rod connecting the hinge-collars to the crank-shaft; a sprocket-wheel upon the rear axle; a sprocket-wheel upon the crank-shaft; and a chain connecting the sprocket-wheel on the crank-shaft with the sprocket-wheel on the rear axle, so that the sprocket-chain is loosened or tightened, substantially as specified.

2. In a motor-vehicle, a running-gear having the forward axle and rear axle rigidly connected by hinged rockers; springs pivotally mounted upon said axle; hinges extending forwardly from said springs; a wagon-bed connected to said hinges; a crank-shaft mounted in the frame or wagon-bed; a sprocket-wheel upon said crank-shaft; a sprocket-wheel upon the rear axle; a chain connecting said sprocket-wheels; and an adjustable or turntable connection between the running-gear and the bed as required to move the running-gear forwardly or backwardly in a body relative to the bed, so as to tighten or loosen the sprocket-chain, substantially as specified.

698,910. CONVEYER ATTACHMENT FOR MIXING-MACHINES OR THE LIKE. GEORGE T. DRAKE, Chicago, Ill. Filed June 7, 1901. Serial No. 95,929. (No model.)

Claim.—1. In combination with a mixer or the like, a turn-table thereon, brackets on the turn-table, side bars pivoted to said brackets, a

rotatable shaft extending through and constituting a pivotal connection between said side bars and brackets, a roller mounted at the end of said side bars, a corresponding roller mounted in the brackets beneath the discharging end of the mixer and beyond the pivotal points of the side bars, a conveyor-belt passing over said rollers, means for communicating power to said rotatable shaft, and driving instrumentalities for operating said belt from said rotatable shaft, substantially as described.

2. In combination with a mixer, a conveyor comprising a suitable support, brackets on said support, a roller mounted in said brackets, a supporting-frame, a roller mounted at the free end of said frame, a conveyor-belt passing around the two rollers, and a rotatable shaft extending through and constituting a pivotal connection between the supporting-frame and the brackets located at a point intermediate the rollers, and driving mechanism for operating the belt from said rotatable shaft, substantially as described.

3. In combination with a mixer, a conveyor comprising a suitable support, brackets on said support, a roller mounted in said brackets, side bars, a roller mounted at the end of said side bars, a belt passing around both rollers, a pivotal connection between the side bars and the brackets comprising projecting studs on the side bars, and spindles on the brackets in which the studs are adapted to rotatably engage, substantially as described.

4. The combination with a mixer, of a turn-table mounted thereon beneath the discharging end thereof, brackets secured to and extending outwardly from said turn-table, a conveyor-frame pivotally supported by said brackets, a conveyor-belt guided upon said frame, a motor mounted upon said turn-table intermediate of said brackets, and power connections between said motor and conveyor-belt whereby the latter is driven.

5. The combination with a mixer, of a turn-table mounted thereon beneath the discharging end thereof, brackets secured to and projecting outwardly from said turn-table and adapted to be shifted therewith, a conveyor-frame pivotally secured to said brackets, guide-rollers in said brackets and said frame, an endless conveyor-belt passing around said rollers, and a motor operatively connected to said conveyor-belt and mounted upon the turn-table so as to be shifted therewith.

6. In combination with a mixer or the like, a conveyor projecting outwardly therefrom, means for permitting a lateral swinging movement thereof, means for permitting a vertical swinging movement thereof, means for raising and lowering the conveyor comprising a rope communicating with the outer end thereof, vertical standards on the mixer-frame, means supported by said standards for operating said rope, and a pair of vertical guides and a horizontal guide supported by said standards between which the rope passes to preserve a proper alignment between said operating-rope and its operating means irrespective of the lateral movement of the conveyor, substantially as described.

7. In a device of the character described, the combination with a suitable support, of side bars pivotally connected to said support, guide-rollers journaled in said support and in the outer ends of said side bars respectively, a rotatable shaft passing through said side bars and said support and constituting the pivotal connection between said bars and support, a conveyor-belt passing around said rollers, sprocket-wheels on one end of said shaft and the corresponding end of the roller journaled in the outer end of said side bars, a sprocket-chain connecting said sprocket-wheels, means for imparting a proper tension to the conveyor-belt and to the sprocket-chain comprising journal-bases for the roller slightly mounted in the ends of the side bars, means for adjusting said bases, and means for communicating power to said rotatable shaft, substantially as described.

8. In combination with a mixer or the like, a turn-table mounted thereon, brackets on said turn-table, a supporting-frame secured to said brackets, rollers in the supporting-frame and brackets respectively, a conveyor-belt passing around said rollers, means for operating said conveyor-belt, and a funnel-shaped hopper supported upon the brackets above the belt and adapted to receive the discharge from the mixer, substantially as described.

9. In combination with a mixer or the like, a turn-table mounted thereon, brackets extending from said turn-table, a supporting-frame pivotally connected to said brackets, rollers in the supporting-frame and brackets respectively, a conveyor-belt passing around said rollers, a motor on the turn-table adapted to be shifted therewith, and gearing instrumentalities in communication with the motor and one of the belt-rollers cooperating to operate the belt, substantially as described.

10. In combination with a mixer or the like, a turn-table mounted thereon, brackets on said turn-table, a supporting-frame pivotally connected to said brackets, rollers in said brackets and supporting-frame respectively, a motor mounted on the turn-table and adapted to be shifted therewith, means for establishing communication between said motor and the outer belt-roller comprising a shaft passing through the pivotal points of the supporting-frame and the brackets, sprocket-wheels at the opposite ends of said shaft, a sprocket-wheel on the outer belt-roller, a chain passing

over said last-mentioned sprocket-wheel and one of the sprocket-wheels on the shaft, and a chain passing over the sprocket-wheel at the opposite end of the shaft and in operative connection with the motor, all substantially as shown and described.

698,911. DOUGLAS MIXER AND CONVEYER. EMERY A. DOL, JR., Charleston, S. C. Filed Aug. 29, 1891. Serial No. 73,097. (No model.)

Claim.—1. In a dough mixer and kneader, the combination of a hopper or receptacle, a stationary hollow member therein having openings for the escape of air, and a revolving hollow member therein also having openings for the escape of air and adapted to move past the stationary member, whereby air is sucked into the dough and kneaded therein substantially as described.

2. In a dough mixer and kneader, the combination of a series of hollow members having openings for the escape of air, and a corresponding series of hollow members having openings for the escape of air and adapted to alternate with and work between the first series of members, whereby cavities are alternately formed and closed in the dough and air sucked therein through the hollow members for the purpose and substantially as described.

3. In a dough mixer and kneader, the combination of a series of hollow members, and another series of hollow members adapted to work between and intermediate the first series of members, all said members having openings for the escape of air for the purpose and substantially as described.

4. In a dough mixer and kneader, the combination of a hopper, a stationary series of parallel horizontally-arranged hollow members therein having openings for escape of air, and a movable series of hollow parallel members therein having openings for escape of air adapted to work between and intermediate the first series of members, and means for supplying air, *do.*, to said members, substantially as described.

5. In a dough mixer and kneader, the combination of a hopper, a series of parallel hollow members stationary mounted therein, and a second series of correspondingly-arranged hollow members rotatably mounted in the hopper, the members of one series being arranged to work intermediate the members of the first series, and all having openings for escape of air, with means for rotating the second series of members, substantially as described.

6. In a dough mixer and kneader, the combination of a hopper, a rotatable shaft, hollow arms thereon provided with projecting hollow fingers having openings for the escape of air, and non-rotatable hollow arms provided with hollow fingers having openings for the escape of air cooperating with the rotating arms and fingers, for the purpose and substantially as described.

7. In a dough mixer and kneader, the combination of a hopper, a stationary series of hollow arms provided with parallel hollow fingers, and a series of movable hollow arms provided with hollow fingers adapted to coast with the non-rotating fingers, said arms and fingers having openings for the escape of air, and means for rotating said movable arms and fingers, substantially as described.

8. In a dough mixer and kneader, the combination of a hopper, a hollow shaft therein, a sleeve on said shaft within the hopper provided with radially-projecting hollow arms communicating with the hollow shaft, and parallel series of fingers projecting from said arms, with rotary bases on said shaft comprising hollow radial arms communicating with the shaft and provided with series of hollow parallel fingers adapted to alternate with and pass between the fingers on the first-mentioned arm, said arms and fingers having openings for the escape of air, substantially as described.

9. In a dough mixer and kneader, the combination of a hopper, a feed pipe or nozzle attached thereto, a rotary shaft passing axially through the hopper, a hub or sleeve on said shaft provided with oppositely radially-projecting tubular arms having series of tubular fingers projecting horizontally therefrom, and a hub keyed on the shaft provided with radial tubular arms from which spring horizontally-disposed series of tubular

for fingers adapted to pass between the fingers on the stationary arm, said arms and fingers communicating and having openings for the escape of air, substantially as described.

10. In a dough mixer and kneader, the combination of a hopper, a rotatable shaft, a series of rotating hollow arms thereon provided with projecting hollow triangular fingers having openings for the escape of air, and a series of non-rotatable hollow arms provided with triangular hollow fingers having openings for the escape of air cooperating with the rotating arms and fingers, for the purpose and substantially as described.

11. In a dough mixer and kneader, the combination of a hopper, a stationary series of hollow arms provided with parallel triangular hollow fingers, and a second series of rotating hollow arms provided with triangular hollow fingers adapted to coast with the non-rotating fingers, said fingers having openings for the escape of air in their bases, means for rotating the second series of arms, and means for supplying air, *do.*, to said arms and fingers, substantially as described.

12. In a dough mixer and kneader, the combination of a hopper, a series of parallel horizontally-arranged hollow fingers stationary mounted therein, and a second series of correspondingly horizontally-arranged hollow fingers rotatably mounted in the hopper, the fingers of one series being arranged to work intermediate the fingers of the first series, said arms and fingers being composed of two castings each triangular in cross-section, substantially as described.

13. In a dough mixer and kneader, the combination of a hopper, a feed pipe or nozzle in one side thereof, a rotary shaft passing axially through the hopper, a stationary hub or sleeve loosely mounted on said shaft provided with oppositely radially-projecting tubular arms having series of tubular fingers projecting horizontally therefrom, one of said arms communicating with said nozzle, with a hub keyed on the shaft provided with radial tubular arms from which spring horizontally-disposed series of tubular fingers adapted to pass between the fingers on the stationary arm, all said arms and fingers communicating through their hubs, substantially as and for the purpose set forth.

14. In a dough mixer and kneader, a hollow stirring member composed of two hollow or channelled castings fitted one within the other, so as to leave an air-channel therebetween, substantially as and for the purpose set forth.

15. In a dough mixer and kneader, the combination of a hopper or receptacle, with a hollow stirring member composed of an arm provided with a series of parallel fingers, said arms and fingers being angular in section and composed of two hollow or channelled castings fitted one within the other, substantially as and for the purpose described.

698,912. TRIMMING ATTACHMENT FOR SEWING-MACHINE. BENJAMIN F. DURAND, Paris, France, assignor to The Union Special Sewing Machine Co., Chicago, Ill., a Corporation of Illinois. Filed Apr. 12, 1901. Serial No. 55,000. (No model.)

Claim.—1. The combination with a sewing-machine, of a bracket in sliding connection at its lower and upper ends respectively with the bed-plate and head, means for adjusting the bracket toward and from the needle, means for securing the bracket to the bed when adjusted, and a trimming mechanism mounted on the bracket and operatively connected with a moving part of the sewing-machine, substantially as described.

2. The combination with a sewing-machine, having a feeding mechanism including a feed-roller, of a bracket in sliding connection with the

bed-plate and provided with means for adjusting it laterally toward and from the needle, a pair of toggle-like trimming-jaws mounted on the bracket, and a link connection between one of the jaws and the feed-roller of the machine to operate the trimming-jaws, and permit adjustment of the bracket, substantially as described.

3. The combination with a sewing-machine, of a bracket in sliding connection with the bed-plate and provided with means for adjusting it laterally toward and from the needle, a pair of toggle-like trimming-jaws mounted on the bracket, and a link pivoted to one of said jaws, and having a pivotal and sliding connection with the feed-roller of the sewing-machine, substantially as described.

4. The combination with a sewing-machine, including a feed-roller at the rear, provided with an arm having a forked upper end, of a bracket in sliding connection with the bed-plate and machine-head as at *a*, means for adjusting the bracket laterally toward and from the needle, toggle-like trimming-jaws mounted on the bracket, and a link pivoted at its forward end to one jaw and at its rear end provided with a pivot-pin turning and sliding in said forked feed-roller arm, substantially as described.

698,913. CULTIVATOR. WILLIAM C. SWANER, Astoria, Ore. Filed Jan. 15, 1891. Serial No. 49,295. (No model.)

Claim.—1. In combination with the triangular frame of the walking-cultivator, the draft appliance at the apex of the frame, the cultivator-shovels applied to the sides of the frame, the supporting-wheels at the rear end of each side of the frame, and the steering-wheel located at the rear end of the frame and arranged intermediate of the supporting-wheels, and consisting of a peripherally-sharpened rotary disk, and a hand-operated tiller connected rigidly to the steering-wheel frame and extending rearwardly therefrom.

2. In a cultivator, the combination with a triangular frame, cultivator-shovels located at opposite sides of the frame and flukes carried by the frame and disposed at the outer sides of the shovels and in close proximity to the ground, of a steering-wheel located at the rear end of the frame and having a sharpened periphery designed to enter the ground, means for shifting the position of the steering-wheel to guide the cultivator without necessity for tilting the latter, and supporting devices for the cultivator-frame, said devices being located at the rear end of the frame and at opposite sides of the steering-wheel, to prevent the tilting of the cultivator-frame, whereby the flukes are prevented from entering the ground, and the steering-wheel is prevented from penetrating the ground to more than a predetermined depth.

3. In a cultivator, the combination with a triangular frame, cultivator-shovels carried at the opposite sides thereof, and flukes carried to the opposite sides of the cultivator-frame in advance of the shovels, and extending obliquely beyond the outer sides of the shovels and in close

proximity to the ground, of a steering-wheel located at the center of the rear end of the frame to guide the cultivator without necessitating tilting of the latter, said steering-wheel having a sharpened periphery designed to enter the ground, vertically-disposed cheeks located in the opposite sides of the rear end of the frame, supporting-wheels carried by said cheeks to prevent the tilting of the frame, and the penetration of the ground by the fender, said supporting-wheels also serving to limit the penetration of the ground by the steering-wheel, and means for shifting the steering-wheel to effect the steering of the cultivator.

698,914. **GRASS-DRIVING APPARATUS.** GEORGE F. FISHER, New London, Conn. Filed Apr. 19, 1901. Serial No. 94,692. (No model.)

Claim.—1. A delivery apparatus for printing-machines comprising a reciprocating tape-carriage and tape-roller, and a pressure-roller made to act on a tape-roller to one side of the tape line so as to cause a sheet having the tape-roller to reverse or curve about said roller substantially as described.

2. A delivery apparatus for printing-machines comprising a reciprocating tape-carriage and tape-roller, a pressure-roller made to act on the tape, a reverser, and a brake or friction appliance made to engage one of the rollers for checking the movement of the tape substantially as described.

3. A delivery apparatus comprising a reciprocating tape-carriage and tape-roller, a pressure-roller made movable toward and from the tape, a reverser or curler, and a support or bracket for the pressure-roller and reverser carried by said carriage substantially as described.

4. A delivery apparatus comprising a reciprocating tape-carriage provided with tape-roller and tape, a ratchet-and-gear connection for one of the rollers to give increased speed to the tape during the forward travel of the carriage, and a sheet-reverser substantially as described.

698,915. **CAR-FENDER.** WILLARD F. FINE, Boston, Mass. Filed July 15, 1900. Serial No. 23,398. (No model.)

Claim.—1. The combination with a car-platform and supports thereunder, of a fender pivotally engaged with said supports and slidable thereon to and from a position beneath the car-platform; latching means normally holding the front of the fender elevated; and means for releasing said latching means, substantially as described.

2. The combination with a car-platform and supports thereunder, of a fender pivotally engaged with said supports and slidable thereon to and from a position beneath the car-platform; latching means normally holding the front of the fender elevated; and a fender extending forwardly beyond the fender and being inwardly movable relative thereto, said fender engaged with the support arm, substantially as described.

3. The combination with a car-platform and supports thereunder, of a fender pivotally engaged with said supports and slidable thereon to and from a position beneath the car-platform; latching means normally holding the front of the fender elevated; and comprising a weighted swinging arm depending from the car-platform and having a catch; and means for releasing said latching means.

4. The combination with a car-platform and supports thereunder, of a fender pivotally engaged with said supports and slidable thereon to and from a position beneath the car-platform; latching means normally holding the front of the fender elevated; and comprising a weighted swinging arm depending from the car-platform and having a catch; and a fender extending forwardly beyond the fender and being inwardly movable relative thereto, said fender engaged with the support arm, substantially as described.

5. A car-fender pivotally engaged with its support at the rear, a latch for holding it in raised position, and means for releasing the latch by the operation thereof of the power-controller.

6. The combination with a car-platform and supports thereunder, of a fender pivotally engaged with said supports and slidable thereon to and from a position beneath the car-platform; latching means normally holding the front of the fender elevated; and means operated by the power-controller for releasing said latching means, substantially as described.

7. A car-fender pivotally engaged with its support at the rear, a latch for holding it in raised position, and means for releasing the latch by the operation thereof of the power-controller; said means comprising a vertical rock-shaft having an arm at its upper end extending in the path of the controller-handle, and suitable connection between said shaft and the latch, substantially as described.

8. The combination with a car-platform and supports thereunder, of a fender pivotally engaged with said supports and having a rearward projection; a weighted arm having a catch to engage said projection and hold the forward part of the fender elevated; a vertical shaft extending through the car-platform and alongside the controller and having an arm at the upper end projecting into the path of the controller-handle and a crank-arm at its lower end; and a rod connecting said crank-arm with the weighted arm, substantially as and for the purpose described.

9. The combination with a car-platform and supports thereunder, of a fender pivotally engaged with said supports; a latch for holding the fender normally elevated; a fender projecting in front of the fender and movable relatively thereto, said fender engaging the latch; and means connected with the latch and cooperating with the controller, substantially as described.

698,916. **BREAD-CUTTER.** AUGUST FIEBIGER, Remer, Germany. Filed Dec. 5, 1901. Serial No. 94,947. (No model.)

Claim.—In a bread-cutter, the combination with a base-plate having at one end a slot A, of feet c having three upwardly-extending elongations, shaft b connecting said feet, a ledge d connecting two of said elongations, and a knife or blade attached to the third elongation, all the movable parts thus constructed being adapted to be turned so as to bring the blade opposite, and into, said slot, as set forth.

698,917. **BANDAL.** JAMES F. PATT, Chicago, Ill., assignor of one-half to John Keller, Chicago, Ill. Filed Nov. 15, 1901. Serial No. 95,704. (No model.)

Claim.—1. In a model designed to be secured to the bottom of a boat or ship, in combination, a cable and a heel portion of wood connected by an insulating portion, the cable portion comprising a plurality of articulated sections, a wire passing through the sections and secured at its ends to the cable-sections adjacent to the insulating portion a two-rod, and a clamp for securing the model in place.

2. In a model, in combination, a cable and a heel portion of wood connected by an insulating portion, the cable portion comprising a plurality of sections one end of each section having a curved transverse groove which receives the rounded end of the adjacent section, a wire passing through the sections and connecting them to the insulating portion, and a clamp for securing the model to a ship.

698,918. **MACHINE FOR DRIVING LEATHER.** ERNEST FISHER, Cincinnati, Germany. Filed Sept. 24, 1901. Serial No. 75,234. (No model.)

Claim.—1. In a machine for driving leather, the combination, with a ring-shaped knife, of a feed-roller, a shaft supporting the same, a second shaft connected at an angle with the first, a sleeve connected at an angle with the bearing of said second shaft, adjusting means connected with said second shaft, and adjusting means connected with said sleeve, substantially as set forth.

2. In a machine for driving leather, the combination, with a ring-shaped knife and a feed-roller, of a guide-plate, and means for adjusting said guide-plate horizontally or obliquely to said feed-roller, substantially as set forth.

3. In a machine for driving leather, the combination, with an annular driving-knife and means for rotating the same, of a feed-roller provided on an adjustable shaft, a horizontally-arranged guide-plate, means for adjusting said guide-plate in inclined position to said driving-knife, and means for adjusting said feed-roller in parallel position with said guide-plate, substantially as set forth.

4. In a machine for driving leather, the combination, with an annular driving-knife provided with a central spindle, of a driving-shaft having a central socket for said spindle, a threaded sleeve fixed on said driving-shaft, a screw-nut for engaging said threaded sleeve, and a wedge-bar for rotating said screw-nut to impart longitudinal motion to said shaft and driving-knife, substantially as set forth.

698,919. **SKIN-FILLING MACHINE.** LEONARD S. FRIEDMAN, Boston, Ill. Filed June 12, 1901. Serial No. 95,000. (No model.)

Claim.—1. The improved skin-filling machine, comprising a hopper

provided with a discharge-orifice, a fixed cylinder having a coincident opening and a discharge-orifice at the lower side, a rotatable cylinder arranged within the fixed cylinder, and provided with a transverse partition or diaphragm, pistons arranged slidably on opposite sides of the partition, and means for rotating the cylinder containing the pistons and for reciprocating said pistons in opposite directions alternately with each rotation, substantially as shown and described.

2. The improved skin-filling machine, comprising a hopper, a fixed cylinder provided with coincident orifices, a rotatable cylinder arranged in the fixed cylinder and provided with diametrically opposite induction and discharge orifices adapted to be brought into coincidence with the orifices of the fixed cylinder, a horizontal partition arranged in the rotatable cylinder, a rotatable shaft arranged concentrically in the rotatable cylinder, pistons arranged on opposite sides of the partition, a rotatable cam for imparting simultaneous reciprocation to the two pistons in opposite directions, and means for rotating the said shaft and cam, alternately, substantially as shown and described.

3. The improved skin-filling machine, comprising a hopper and a fixed cylinder with two sets of orifices as specified, a rotatable cylinder having two sets of orifices for reception and discharge of the feed article, said orifices being arranged diametrically opposite and adapted to be brought into coincidence with the discharge-orifices of the hopper and fixed cylinder, a longitudinal, central partition arranged in the rotatable cylinder and dividing the same into two compartments, a pair of pistons arranged in the two opposite sets of compartments, those of each pair being on opposite sides of the said partition and duly spaced apart, and means for reciprocating the two sets of pistons simultaneously, but in opposite directions, and for rotating the cylinder with the contained partitions and pistons, the reciprocation and rotation being alternate and both intermittent, substantially as shown and described.

4. In a skin-filling machine, the combination, with a fixed cylinder, of a rotatable cylinder arranged therein, and two semi-cylindrical pistons arranged in said rotatable cylinder, means for reciprocating said pistons, a shaft for rotating the cylinder and its contained pistons, a fixed frame having a removable bar constituting a bearing for said shaft and extending across an opening in said frame, which opening is aligned with the rotatable cylinder and has a greater diameter than the latter, whereby the rotatable cylinder and its attachments may be removed bodily through said opening, substantially as shown and described.

5. In a skin-filling machine, the combination, with a rotatable hopper and a fixed cylinder communicating therewith, of a rotatable cylinder arranged in said fixed cylinder, a shaft for imparting rotation thereto, pistons adapted to slide in the rotatable cylinder, a cam, a sprocket-wheel for rotating the said cam, gearing adapted for rotating said sprocket-wheel and cam alternately, a vertically-adjustable support for each piston and shaft, and the frame or casing having an end opening adapted to permit removal bodily of the rotatable cylinder and its connections, substantially as shown and described.

698,990. DRAFT-SQUAVER. THOMAS F. FOLEY and JAMES J. FOLEY, Dayton, Ohio. Filed Aug. 21, 1901. Serial No. 73,773. (No model.)

Claim.—1. The draft-squaver herein described, consisting of the beam pivoted between its ends, the main beam made longer than the rear beam and arranged at one end in line with the corresponding end of the rear beam and projecting at its other end laterally beyond the corresponding end of the rear beam, the connecting-rod between the said main and rear beams at their ends, one of said connecting-rods extending parallel with the line of draft, and the other connecting-rod extending oblique to the line of draft, and the bearing connected to the main beam relatively near to the end thereof, which is in line with the corresponding end of the rear beam and constructed and adapted to slide along the tongue of the slider, substantially as and for the purposes set forth.

2. In a draft-squaver, the combination substantially as described of the slider-tongue, the rear beam pivoted between its ends thereto, the main beam arranged at one end in line with the corresponding end of the rear beam and extending at its other end laterally beyond the other end of the rear beam, the box on the outer side of the main beam near one end thereof and embracing the slider-tongue whereby the main beam can slide along said tongue, and connections between the ends of the main and rear beams, substantially as set forth.

3. In a draft-squaver, the combination of the slider-tongue, the rear beam pivoted midway between its ends to the slider-tongue, the main beam held to and slidable along the slider-tongue at a point near one end of its end, and devices connecting the ends of the main and rear beams, substantially as set forth.

4. The draft-squaver herein described, comprising the main beam provided near one end with the box and arranged to embrace and slide along the slider-tongue, the rear beam made shorter than the main beam and pivoted between its ends to the slider-tongue at a point in line with the center of the box of the main beam, the rod connections composed of joined sections and secured at their rear ends to the rear beam, and the device connecting the front ends of the rod connections with the main beam, substantially as set forth.

5. A draft-squaver comprising the main beam provided at a point relatively near one end with a box arranged to embrace and slide along the tongue, the rear beam made shorter than the main beam and pivoted between its ends to the tongue at a point approximately in line with the center of the box of the main beam, the rod connections between the main and rear beams at one end thereof and approximately in line with the line of draft, and the opposite rod connection connecting the other ends of the main and rear beams, and arranged obliquely to the line of draft, substantially as set forth.

698,991. BOOK-BINDER. WILLIAM FOLEY, Cincinnati, Ohio. Filed Feb. 17, 1902. Serial No. 94,909. (No model.)

Claim.—In a book, the combination with the stitched signatures and lay-cords thereof, of the stitching-thread formed with a double loop

around the lay-cords at each end of each signature and the intermediate thread drawn through the side of the signature, and looped around the intermediate lay-cord, substantially as shown and described.

698,992. LIFTING-JACK. FRED H. FORD, Jacksonville, Fla., assignor of one-half to John H. Hill, Jacksonville, Fla. Filed Aug. 20, 1901. Serial No. 73,774. (No model.)

Claim.—1. In a lifting-jack, the combination with a frame, of upright posts slidable one in the other, a lever pivoted on the frame, and two pawls carried by the lever and adapted to engage with teeth on the posts for their elevation, substantially as shown and described.

2. In a lifting-jack, the combination with a frame, two posts vertically slidable on the frame one within the other, teeth on said posts, a lever pivoted on the frame adjacent to one end of the lever, a pawl pivoted on the lever at one side of the pivot of said lever, and a shorter pawl pivoted on the lever at the opposite end thereof, said pawls engaging the teeth of the posts.

3. In a lifting-jack, the combination with a frame, of two posts one slidable in the other, a series of teeth on each post, a long pawl, and a shorter pawl respectively pivoted at opposite sides of the lever-pivot, the teeth of the pawls engaging separated teeth on the posts one pawl descending while the other pawl pushes upon a tooth of a post.

4. In a lifting-jack, the combination with a frame, of two posts one slidable in a slot of the other post, a foot-piece projected from one of the posts near its lower end, a series of teeth on each post, a lever pivoted near one end thereof between the sides of the frame, a long pawl pivoted on the lever outside of the frame, another shorter pawl pivoted on the lever at the end that is nearest to the posts, the pawls having engagement with the teeth of the posts but simultaneously moving in opposite directions.

5. In a lifting-jack, the combination with a frame, of two posts one post slidable in the other, a foot-piece extended outwardly from the post that is located in the wider post, a series of downwardly-hooking teeth on the front face of each post, a lever pivoted near one end thereof between the sides of the frame, a long pawl pivoted on the lever inclining upward and toward the teeth of the posts for engagement therewith, a shorter pawl pivoted on the inner end of the lever and at the opposite side of the lever-pivot from that occupied by the pivot of the long pawl, on one pivoted on the lever and having a hook on the free end, and a pin projected at one side of the shorter pawl, whereon the hook of the arm may engage.

6. In a lifting-jack, the combination with a frame, two posts slidable one in the other, and together in the frame, two detent-dogs on one post adapted to engage in notches on the other post near the lower end thereof, and teeth on each of the posts, of a lever pivoted on the frame, adjacent to one end of the lever, a pawl pivoted on the lever at one side of the pivot of said lever, and a shorter pawl pivoted on the lever at the opposite end thereof, the first pawl that is longest engaging the teeth of the posts above the shorter pawl, one pawl acting as a detent while the other pawl is pushing when actuated by the vibration of the lever.

7. In a device of the character described, the combination with a frame, of two lifting-jacks, one sliding in the other, and both posts sliding in the frame, spring-pressed dogs on one post adapted to interlock with shoulders on the other post when it is fully elevated, and means to de-

rate one post to its limit on the other post and then raise both posts together, said means being adapted to releasably secure one post or both posts at a desired elevation on the frame.

698,993. BEER-TAPPING DEVICE. FREDERICK FORD, Brooklyn, N. Y., assignor of one-half to Joseph Ford, Brooklyn, N. Y. Filed Jan. 8, 1902. Serial No. 93,993. (No model.)

Claim.—1. A beer-tapping hammer or mallet which is oblong in form and provided in one side thereof with a longitudinal opening, one of the side walls of said opening being extended and curved in the direction of the other, said hammer or mallet being also provided at one end with projecting members forming a vane, substantially as shown and described.

2. A beer-tapping hammer or mallet which is oblong in form and provided in one side thereof with a longitudinal opening, one of the side walls of said opening being extended and curved in the direction of the other, said hammer or mallet being also provided at one end with projecting members forming a vane, and at the opposite end with projecting lifting hooks or members, substantially as shown and described.

698,994. STAGE ILLUMINATION WITH INDEPENDENT LIGHT. HENRI FORTUIT, Vienna, Italy. Filed Apr. 12, 1901. Serial No. 94,999. (No model.)

Claim.—1. In a stage-illumination apparatus, a movable reflector-screen having a diversely-colored surface, and means for directing rays of light directly onto said colored surface, and the latter serving to direct colored rays onto a desired object.

2. In a stage-illumination apparatus, a reflector-screen having a diversely-colored, translucent surface, a source of light, a reflector arranged to receive the light-rays and to project the same directly onto said colored surface, and the latter serving to direct colored rays onto a desired object.

698,995. AXLE-GRINDER. HARRY POWELL, Cranford, Ind. Filed Aug. 24, 1901. Serial No. 73,115. (No model.)

Claim.—1. An axle-grinder, comprising a tapering body portion of cross-shaped cross-sectional form, and means at the wide end of the shaft removably to hold it against the outer side of the axle-spindle.

2. An axle-grinder, comprising a body portion or shaft proper, an enlarged head at the inner end thereof, a chuck projecting forward longitudinally from the head, for the purpose specified, and side-extensions

best upward and inward from the front of the head to form the chuck lying around the axle.

3. An axle-grinder, comprising a body portion or shaft proper, a lateral flange at its inner end, a head carried on the outer edge of the flange, a chuck carried by the head and projecting inward therefrom for the purpose specified, and side-extensions from the ends of said flange, the extensions being bent upward and inward to form an chuck lying around the axle.

698,996. WINDOW-CURTAIN. RUFUS S. FOWLER, Worcester, Mass., assignor to White A. Dodge and Louis H. Dodge, Kansas, N. H. Filed Dec. 24, 1900. Serial No. 93,994. (No model.)

Claim.—1. The combination with the frame of a window-curtain provided with a slot 16 in its side having a curved bottom, of a yielding latch consisting of a piece of wire provided with a bearing-surface 19 adapted to bear against the window-curtain, an oblique elastic section 17, and a section 18 curved to fit the curved bottom of the slot 16, said curved section being pressed into and pinched between the sides of said slot, whereby said latch is rigidly attached to said frame, substantially as described.

2. The combination with the frame or window-curtain having a slot in its side, of a yielding latch consisting of a piece of wire provided with a section 19 adapted to bear against the window-curtain, an oblique elastic section 17, a curved section 18 entering said slot and being pinched between its sides, whereby said latch is firmly attached to said frame and held from rocking therein, and a bent prong at the end of said curved section entering the frame, whereby said latch is held from longitudinal movement, substantially as described.

3. The combination with the frame of a window-curtain having a slot in its side of a yielding latch formed from a single piece of wire and having a section 18 curved in the arc of a circle with said curved section pinched between the side walls of said slot, whereby said latch is firmly attached to said frame, a section 17 extending obliquely from the frame, a section 19 parallel with the side of the frame and forming a bearing-surface and a stem 21 at right angle to said bearing-surface, substantially as described.

698,997. MUD-PLASTER. ANDREW GALE, Chicago, Ill. Filed July 31, 1901. Serial No. 73,999. (No model.)

Claim.—1. In a mud-plaster or analogous machine, a marker-arm connected at its inner end to a suitable part of the machine by a universal joint and free to be moved in any direction on said joint, a revolute carried by said arm, means preventing rearward movement of the marker-arm when it is brought to operative position, handles on the machine, and means on the handles in engagement with which the marker-arm is adapted to be moved to hold the same in an elevated position.

2. In a mud-plaster or analogous machine, the combination with the frame of the machine, of a marker-arm connected to an intermediate part of the frame by a universal joint and adapted to rest at a point between its ends upon one side or the other of the frame, said arm being free to be moved in any direction upon the universal joint, a revolute carried by said arm, projecting stops one at each side of the frame in front of which the arm is adapted to be engaged when resting on the frame to prevent rearward movement thereof when brought into either of its two operative positions, handles projecting upwardly from the frame, and means on the handles with which the rod is adapted to be engaged to hold the same in an elevated position.

698,998. PLASTER. THOMAS H. GALLAGHER, Old Orchard, Me., assignor to Gault-Gallagher Iron & Steel Company, St. Louis, Mo., a Corporation. Filed Oct. 24, 1901. Serial No. 73,998. (No model.)

Claim.—1. A plaster, consisting of a top, side flanges, a central

flange and spring-ends uniting the bottom of the flange at the ends of the bolster, all cast integral, substantially as set forth.

2. A bolster, consisting of a top, side flange, a central flange, spring-ends uniting the bottom of the flange together at the ends of the bolster, a king-bolt post, and a web connecting the post to the side flange of the bolster, all cast integral, substantially as set forth.

698,989. BODY-BOLSTER FOR RAILWAY-CARS. THOMAS H. GALLAGHER, Old Orchard, Mo., assignor to Smith-Gallagher Iron & Steel Company, St. Louis, Mo., a Corporation. Filed Dec. 20, 1901. Serial No. 57,060. (No model.)

Claim.—1. A body-bolster for railway-cars, consisting of a top, outer vertical rib and an intermediate rib depending from the top, and side bearings uniting the ribs at their lower edges, substantially as described.

2. A body-bolster for railway-cars consisting of a top, outer and intermediate ribs depending from the top, and outer and side bearings uniting the ribs at their lower edges, substantially as described.

3. A body-bolster for railway-cars consisting of a top, two outer vertical ribs depending from the top, and central intermediate vertical ribs depending from the top, and integral side and outer bearings connecting all three of said ribs together at their lower edges, substantially as set forth.

4. A body-bolster for railway-cars consisting of a top, vertical ribs depending from the top and forming the sides of the bolster, a center bearing uniting the ribs at their lower edges, a king-bolt post uniting the center bearing with the top of the bolster, and a web connecting the king-bolt post with the outer vertical ribs, substantially as set forth.

698,980. WHEELBARROW. EDWARD A. GARVER and DONALD V. STROT, Chicago, Ill. Filed Sept. 6, 1901. Serial No. 74,519. (No model.)

Claim.—1. A wheelbarrow-frame comprising combined upper side and handle bars, combined lower side bars and supporting-legs, a wheel, front and rear tray-supporting side braces adjustably secured to the combined upper side and handle bars and to the combined lower side bars and supporting-legs and connecting-braces secured to the forward ends of the said combined upper side and handle bars and to the forward ends of the combined lower side bars and supporting-legs, substantially as set forth.

2. A wheelbarrow-frame comprising combined upper side and handle bars, combined lower side bars and supporting-legs, cross-braces adjustably secured to the combined upper side and handle bars and to the combined lower side bars and supporting-legs for spacing them apart and

side braces secured to the said combined upper side and handle bars and combined lower side bars and supporting-legs, substantially as set forth.

3. A wheelbarrow-frame comprising combined upper side and handle bars, combined lower side bars and supporting-legs, cross-braces adjustably secured to the combined upper side and handle bars and to the combined lower side bars and supporting-legs and side braces adjustably secured to the combined upper side and handle bars and to the combined lower side bars and supporting-legs, substantially as set forth.

4. A wheelbarrow-frame comprising combined upper side and handle bars, combined lower side bars and supporting-legs, cross-braces adjustably secured to the combined upper side and handle bars and to the combined lower side bars and supporting-legs, front and rear side braces adjustably secured to the combined upper side and handle bars and to the combined lower side bars and supporting-legs and connecting-braces secured to the forward ends of the combined upper side and handle bars and the combined lower side bars and supporting-legs, substantially as set forth.

698,981. ELECTRIC-ARC LAMP. CLARE CLARK, Bridgeport, Ohio. Filed Jan. 12, 1902. Serial No. 1,264. (No model.)

Claim.—In an electric-arc lamp, the combination of a series coil having a fine-wire coil 5 wound within it, a lever, a soft-iron core mounted on said lever and movable within said fine-wire coil, a friction-clutch, a toggle-arm pivoted to one end of said lever and supporting said friction-clutch, said fine-wire coil being adapted to demagnetize said soft-iron core when the arc becomes too long, permitting said clutch to free itself from the upper carbon and allowing the lamp to feed automatically, and an adjusting-screw 17 for regulating the magnetic linkage, substantially as and for the purposes set forth and described.

698,982. GLASS-MAKING FURNACE. EARL GOSSE, Junot, Belgium. Filed Aug. 6, 1901. Serial No. 71,000. (No model.)

Claim.—In a glass-making furnace, the combination with a tank adapted to be revolved and carry pots containing the material to be melted, refined and cooled, of means for forming a high-temperature zone in one portion of the furnace for melting and refining the material contained in the pots, means for forming a low-temperature zone in the other portion of the furnace for cooling the melted and refined material, and means to permit of access to the furnace for removing the pots after the material has been melted, cooled and refined, and for the replacing of the pots containing the material to be operated upon.

698,988. PACKAGE-CARRIER. OVID H. GOULA, Montreal, Canada. Filed July 22, 1901. Serial No. 60,968. (No model.)

Claim.—1. A package-carrier comprising a pair of carriers proper alternating toward and from one another, stationary means whereby a package is fed to one of said carriers proper when it is at its extreme position away from the other carrier proper, means stationary relatively to said first-mentioned carrier proper whereby said package is shifted from said first-mentioned carrier proper to said other carrier proper when they are adjacent to one another, and means stationary relatively to said other carrier proper whereby said package is discharged from said other carrier proper when it is at its extreme position away from said first-mentioned carrier proper, means for controlling the speed of the carriers proper in their movement, for the purposes set forth.

2. A package-carrier comprising a pair of carriers proper alternating toward and from one another, stationary means whereby a package is automatically fed to one of said carriers proper when it is at its extreme position away from the other carrier proper, means stationary relatively to said first-mentioned carrier proper whereby said package is automatically shifted from said first-mentioned carrier proper to said other carrier proper when they are adjacent to one another and means stationary relatively to said other carrier proper whereby said package is automatically discharged from said other carrier proper when it is at its extreme position away from said first-mentioned carrier proper, for the purposes set forth.

3. A package-carrier comprising a pair of carriers proper alternating toward and from one another, stationary means whereby a package is fed to one of said carriers proper when it is at its extreme position away from the other carrier proper, means stationary relatively to said first-mentioned carrier proper whereby said package is shifted from said first-mentioned carrier proper to said other carrier proper when they are adjacent to one another, means stationary relatively to said other carrier proper whereby said package is discharged from said other carrier proper when it is at its extreme position away from said first-mentioned carrier proper, and means for automatically counting and registering the number of the packages so carried, for the purposes set forth.

4. A package-carrier comprising a pair of carriers proper alternating toward and from one another, stationary means whereby a package is automatically fed to one of said carriers proper when it is at its extreme position away from the other carrier proper, means stationary relatively to said first-mentioned carrier proper whereby said package is automatically shifted from said first-mentioned carrier proper to said other carrier proper when they are adjacent to one another, means stationary relatively to said other carrier proper whereby said package is discharged from said other carrier proper when it is at its extreme position away from said first-mentioned carrier proper and means for automatically counting and registering the number of the packages so carried, for the purposes set forth.

5. A package-carrier consisting of a pair of carriers proper hung

upon one another and movable vertically simultaneously respectively toward and from a common level; stationary means whereby a package is fed to the uppermost of said carriers proper when they have moved away from their common level; means stationary relatively to said first-mentioned carrier proper whereby said package is shifted to the other carrier proper when said carriers are at their common level; and means stationary relatively to said other carrier proper whereby said package is discharged from said last-mentioned carrier proper when at its lowest level, substantially as described and for the purposes set forth.

6. A package-carrier consisting of a pair of carriers proper hung upon one another and movable vertically simultaneously respectively toward and from a common level; stationary means whereby a package is fed to the uppermost of said carriers proper when they have moved away from their common level; means stationary relatively to said first-mentioned carrier proper whereby said package is shifted to the other carrier proper when said carriers are at their common level; means stationary relatively to said other carrier proper whereby said package is shifted from said last-mentioned carrier proper when at its lowest level; and means for counting and registering the number of packages discharged, substantially as described and for the purposes set forth.

7. A package-carrier consisting of a vertical shaft having a discharge-opening in one side of its lower end; a vertical partition dividing said shaft longitudinally and parallel to the side having said opening therein and having an opening about midway of the height of said shaft; a pair of carriers proper hung upon one another and vertically slidable in the divided portions of said shaft; a runway located at the top of the shaft and leading to the side thereof opposite to that in which the discharge-opening is out; a movable stop extending across said runway; means to at intervals move said stop; means whereby a package is automatically moved from one to the other of said carriers proper; and means whereby the package thus moved is discharged from the carrier proper to which it is then moved, substantially as described and for the purposes set forth.

8. A package-carrier consisting of a vertical shaft having a discharge-opening in one side of its lower end; a vertical partition dividing said shaft longitudinally and parallel to the side having said opening therein, and having an opening about midway of the height of said shaft; a pair of carriers proper hung upon one another and vertically slidable in the divided portions of said shaft; sprocket-wheels mounted above the divided portions of said shaft one in vertical line with each carrier proper; a chain connected at its ends to said carriers proper and hung over said sprocket-wheels; a runway located at the top of the shaft and leading to the side thereof opposite to that in which the discharge-opening is out; a movable stop extending across said runway; means to at intervals move said stop; means whereby a package is automatically moved from one to the other of said carriers proper; and means whereby the package thus moved is discharged from the carrier proper to which it is then moved, substantially as described and for the purposes set forth.

9. A package-carrier consisting of a vertical shaft having a discharge-opening in one side of its lower end; a vertical partition dividing said shaft longitudinally and parallel to the side having said opening therein, and having an opening about midway of the height of said shaft; a pair of carriers proper vertically slidable in the divided portions of said shaft; sprocket-wheels mounted above the divided portions of said shaft one in vertical line with each carrier proper; a chain connected at its ends to said carriers proper and hung over said sprocket-wheels; a runway located at the top of the shaft and leading to the side thereof opposite to that in which the discharge-opening is out; a movable stop extending across said runway; means for causing said carriers to at intervals move said stop; means whereby a package is automatically moved from one to the other of said carriers proper; and means whereby the package thus moved is discharged from the carrier proper to which it is then moved, substantially as described and for the purposes set forth.

10. A package-carrier consisting of a vertical shaft having a discharge-opening in one side of its lower end; a vertical partition dividing said shaft longitudinally and parallel to the side having said opening therein, and having an opening about midway of the height of said shaft; a pair of carriers proper vertically slidable in the divided portions of said shaft; sprocket-wheels mounted above the divided portions of said shaft one in vertical line with each carrier proper; a chain connected at its ends to said carriers proper and hung over said sprocket-wheels; a runway located at the top of the shaft and leading to the side thereof opposite to that in which the discharge-opening is out; a movable stop extending across said runway; means for causing said carriers to at intervals move said stop; means whereby a package is automatically moved from one to the other of said carriers proper; and means whereby the package thus moved is discharged from the carrier proper to which it is then moved, substantially as described and for the purposes set forth.

11. A package-carrier consisting of a vertical shaft having a discharge-opening in one of its lower ends; a vertical partition dividing said shaft longitudinally and parallel to the side having said opening therein, and having an opening about midway of the height of said shaft; a pair of carriers proper vertically slidable in the divided portions of said shaft;

sprocket-wheel mounted above the divided portion of said shaft one in vertical line with each carrier proper; a chain connected at its ends to said carriers proper and hung over said sprocket-wheel; a runway located at the top of the shaft and leading to the side thereof opposite to that in which the discharge-opening is out; a movable stop extending across said runway; means for causing said carriers to at intervals move said stop; means whereby a package is automatically moved from one to the other of said carriers proper; means whereby the package thus moved is discharged from the carrier proper to which it is thus moved; and means for counting and registering the number of the packages discharged, substantially as described and for the purpose set forth.

12. A package-carrier consisting of a vertical shaft having a discharge-opening in one side of its lower end; a vertical partition dividing said shaft longitudinally and parallel to the side having said opening therein, and having an opening about midway of the height of said shaft; a pair of carriers proper vertically slidable in the divided portions of said shaft; and each having an inclined platform; a sprocket-wheel mounted above the divided portion of said shaft one in vertical line with each carrier proper; a chain connected at its ends to said carriers proper and hung over said sprocket-wheel; a runway located at the top of the shaft and leading to the side thereof opposite to that in which the discharge-opening is out; a movable stop extending across said runway; means for causing said carriers to at intervals move said stop; substantially as described and for the purpose set forth.

13. A package-carrier consisting of a vertical shaft having a discharge-opening in one side of its lower end; a vertical partition dividing said shaft longitudinally and parallel to the side having said opening therein, and having an opening about midway of the height of said shaft; a pair of carriers proper vertically slidable in the divided portions of said shaft; and each having an inclined platform; a sprocket-wheel mounted above the divided portion of said shaft one in vertical line with each carrier proper; a chain connected at its ends to said carriers proper and hung over said sprocket-wheel; a runway located at the top of the shaft and leading to the side thereof opposite to that in which the discharge-opening is out; a movable stop extending across said runway; means for causing said carriers to at intervals move said stop; and means for counting and registering the number of the packages discharged, substantially as described and for the purpose set forth.

14. A package-carrier consisting of a vertical shaft having a discharge-opening in one side of its lower end; a vertical partition dividing said shaft longitudinally and parallel to the side having said opening therein, and having an opening about midway of the height of said shaft; a pair of carriers proper vertically slidable in the divided portions of said shaft; a sprocket-wheel mounted above the divided portion of said shaft one in vertical line with each carrier proper; a chain connected at its ends to said carriers proper and hung over said sprocket-wheel; a runway located at the top of the shaft and leading to the side thereof opposite to that in which the discharge-opening is out; a movable stop extending across said runway; means whereby a package is automatically moved from one to the other of said carriers proper; and means whereby the package thus moved is discharged from the carrier proper to which it is thus moved; a yielding platform adjacent to said discharge-opening; a counting and registering device; and an operative connection between said yielding platform and said counting and registering device, substantially as described and for the purpose set forth.

15. A package-carrier consisting of a vertical shaft having a discharge-opening in one side of its lower end; a vertical partition dividing said shaft longitudinally and parallel to the side having said opening therein, and having an opening about midway of the height of said shaft; a pair of carriers proper vertically slidable in the divided portions of said shaft; and each having an inclined platform; a sprocket-wheel mounted above the divided portion of said shaft one in vertical line with each carrier proper; a chain connected at its ends to said carriers proper and hung over said sprocket-wheel; a brake for controlling the movement of said chain, a runway located at the top of the shaft and leading to the side thereof opposite to that in which the discharge-opening is out; a movable stop extending across said runway; means for causing said carriers to at intervals move said stop; a yielding platform adjacent to said discharge-opening; a counting and registering device; and an operative connection between said yielding platform and said counting and registering device, substantially as described and for the purpose set forth.

698,984. **TYRAN CONNECTION.** JAMES R. GUNTER; Inventor. Filed Feb. 27, 1902. Serial No. 55,567. (No model.)

Claim.—1. In a piano connection, the combination with the piano-red, of plates attached to the sides of the piano-red and projecting beyond the end thereof, said plates having caps at their free ends and in the rear of said caps provided with hyaline-dots, there being inclined

flats on the outer sides of the plates and surrounding the circular portions of said hyaline-dots, and a locking-bar having tongues spaced apart, said tongues being adapted to ride upon the inclined surfaces and thereby move the plates toward each other, together with means for holding the locking-bar adjusted.

2. In a piano connection, the combination with the piano-red, of plates attached to the sides of the piano-red and projecting beyond the end thereof, one of the plates being hinged at its inner end and both provided with caps at their outer ends and in the rear of said caps with openings having a surrounding inclined surface, a locking-bar having tongues spaced apart and adapted to ride upon the inclined surfaces of the plates, and means for holding the locking-bar.

3. In a piano connection, the combination with the piano-red, of plates attached to the sides of the piano-red and projecting beyond the end thereof, one of the plates being hinged at its inner end and provided with short pins engaging corresponding holes in the piano-red, caps at the free ends of said plates, each plate having a hyaline-dot and on its outer side an inclined surface surrounding the circular portion of the hyaline-dot, and a locking-bar mounted in the hyaline-dot and provided with tongues spaced apart and adapted to ride upon the inclined surfaces and bring the caps toward each other, together with means for holding the locking-bar.

4. In a piano connection, the combination with the piano-red, of plates attached to the sides of the piano-red and provided with caps and with openings having corresponding inclined surfaces on the outer sides of the plates, a locking-bar mounted in the openings and provided with tongues adapted to ride upon the inclined surfaces and move the caps toward each other, a ratchet-wheel on the locking-bar, a pawl carried by one of the plates and engaging said ratchet-wheel, and a handle formed on or attached to the end of the locking-bar, substantially as shown and described.

5. In a piano connection, the combination with the piano-red, of plates attached to the sides of said piano-red, one of the plates being hinged at its inner end, caps at the outer end of the plates, there being inclined surfaces surrounding openings in the plates, a locking-bar mounted in said openings, tongues of the locking-bar adapted to ride upon the inclined surfaces, a ratchet-wheel on the locking-bar, a pawl adapted to engage the ratchet-wheel, and a handle or lever connected to one end of the locking-bar, substantially as shown and for the purpose set forth.

698,985. **BOX-CRATE.** RAIN J. HANSEN; Inventor. Filed Oct. 25, 1901. Serial No. 55,570. (No model.)

Claim.—1. A crate, having a rigid framing made up of top and bottom sections connected together by corner-posts and side rails arranged horizontally with spaces between them, and drawers mounted in the framing, each drawer comprising side and end walls and a bottom, the side edges of which are projected beyond the side walls to enter the spaces between the rails, whereby to guide the drawers in their movement into and out of the frame and to hold the drawers properly spaced therein.

2. A crate, having a rigid framing made up of top and bottom sections connected together by corner-posts and side rails arranged horizontally with spaces between them, drawers mounted in the framing, each drawer comprising side and end walls and a bottom, the side edges of which are projected beyond the side walls to enter the spaces between the rails, whereby to guide the drawers in their movement into and out of the frame and to hold the drawers properly spaced therein, and a lock-rod removably fitted in the frame, said rod extending vertically in front of the drawers to hold them in place.

3. A crate, comprising a framing having an open end, drawers removably fitted in the framing, and a lock-rod removably mounted in openings in the top and bottom of the frame directly in front of the drawers to hold them in place, said lock-rod extending vertically from the top to the bottom of the frame.

4. A crate, comprising a framing having an open end and rigidly connected top and bottom sections, reinforcing-plates fastened respectively to said sections at the adjacent or inner ends thereof, drawers fitted in the frame, and a lock-rod passed through openings in the top section of the frame and in the reinforcing-plates thereof and extending downward into an opening in the reinforcing-plate of the bottom section of the frame, said lock-rod passing directly in front of the drawers, to hold them in place.

5. A crate, having a rigid framing, comprising side rails arranged horizontally with spaces between them, and drawers mounted in the framing, each drawer comprising side and end walls and a bottom, the side edges of which bottom are projected beyond the side walls to enter the spaces between the rails, whereby to support the drawers and guide them in their movement into and out of the frame and to hold the drawers properly spaced therein.

698,986. **SAW-HANDLE CLAMP.** JOHN A. HALL; Inventor. Filed Aug. 22, 1901. Serial No. 55,568. (No model.)

Claim.—1. A saw-handle clamp, comprising two jaws, a bolt rotatably connecting said jaws, a cam-lever adapted to draw opposed ends of the jaws toward each other, and a handle-bar clamped between the jaws.

2. A saw-handle clamp, comprising two jaws, a bolt rotatably connecting said jaws, a cam-lever projecting from the outer side of one jaw, a cam-lever pivoted on the bolt and adapted to press the cam-lever when rotated toward it, and a handle-bar clamped between the jaws.

3. A saw-handle clamp, comprising two jaws adapted to receive the stub end of a saw-blade between inner faces of their forward ends, studs on one of said jaws that may pass through perforations in the stub end, a bolt rotatably connecting said jaws, a cam-lever projected from the outer side of one jaw, a cam-lever pivoted on the bolt and adapted to press the cam-lever when rotated toward it, and a handle-bar clamped in grooves apertures formed in the jaws and extended upright therefrom.

698,987. **CLIP FOR FLOWS OR THE LIKE.** BROWN HALL; Inventor. Filed May 1, 1901. Serial No. 55,569. (No model.)

Claim.—1. In a clip, a clasp, and an over-ear hook having jaws embracing the clasp, said jaws having interior ribs to bear on the clasp and limit the lateral swing of the hook.

2. In a clip, a clasp having a vertically-disposed series of bulb-holes and a rib in front of said bulb-holes, and an over-ear hook having jaws with inner projections to bear on the clasp-rib, whereby its lateral swing is limited.

3. The combination of the clasp having the strengthening-rib 8, and the hook having jaws 6 grooved at 7 to receive said rib.

4. The hook having jaws with interior ribs 12 separating the openings 9 and 10, and the clasp having a front bar provided with a rib 11, the relative movement of the hook being limited by the contact of the rib 11 with other rib 12.

5. The hook having jaws with interior ribs 12 separating the openings 9 and 10, and the clasp having a front bar provided with a rib 11, the relative movement of the hook being limited by the contact of the rib 11 with other rib 12, and the outer ribs 13 of said front bar situated in the path of the jaw-tips and cooperating to stop the lateral movement of the hook.

6. A clasp pivoted to a pivot-beam, a rotatable clasp-rotating rod having a screw-thread connection with a nut loosely supported by the beam, and a nut loosely supported by the clasp and retained by the rod to rotate the clasp.

7. A pivot-beam, a clasp pivoted thereto, a nut loosely supported by the beam, a nut rotatably supported by the clasp, and a clasp-rotating rod having right and left hand screw-threads engaging respectively the two nuts.

8. A pivot-beam, a clasp pivoted thereto, a nut loosely supported

by the beam, a nut rotatably supported by the clasp, and a rod having (similar screw-threads engaging each of the nuts and adapted to rotate the clasp.

9. A pivot-beam, a clasp pivoted thereto, a nut loosely supported by the beam, a nut rotatably supported by the clasp, a clasp-rotating rod having right and left hand screw-threads engaging respectively the two nuts, and the handle, said rod comprising parts 15 and 17 connected by the universal joint 16 situated between the beam-supported nut and the handle.

698,988. **MEANS FOR TEACHING WRITING.** PARKER S. HALL; Inventor. Filed Nov. 23, 1901. Serial No. 55,569. (No model.)

Claim.—In the means for teaching writing, a sheet provided with the copy and having a slit parallel with and adjacent to the copy and having circular openings at the ends of the slit, and a practice-sheet to be moved through the slit, substantially as set forth.

698,989. **BOOK CLIPPING AND BINDER DEVICE.** JAMES L. HALL; Inventor. Filed Apr. 4, 1901. Serial No. 55,561. (No model.)

Claim.—The combination with a revolving door adapted to move only in a horizontal plane and provided with a mortise at its lower edge; of a slotted casing within said mortise, a spring-pressed plunger within the casing, a roller carried by said plunger, a plate mounted below the door, an oppositely-located trackway upon the plate having notches therein, a corner-plate secured to the door, and a plate depending from said corner-plate and adapted to bear in a contact in the plate of the trackway, said trackway being adapted to gradually move the roller and plunger toward and compress their spring during the opening of the door.

698,989.

698,940. LATCH. THOMAS C. HAMILTON, Bates Creek, Ohio. Filed June 28, 1901. Serial No. 66,577. (No model.)

Claim.—The combination with a hinged gate having horizontal rails, of a post, a horizontal strip secured thereto, and extending from opposite sides thereof, a bolted end to the strip, a brace connecting the opposite end to the post, said strip being adapted to project through the closed gate at a point between its ends and partly support the same, a latch pivotally mounted upon the strip adjacent to the bolted end thereof, an inclined face thereon, an end to the latch adapted to automatically engage one of the rails of the gate when closed, and a handle extending longitudinally from the end of the latch and adapted to project through the gate and limit the downward movement of the latch.

698,941. ROYAL-WHEEL HUB. LEON C. HANNA, Tampa, Fla. Filed Feb. 6, 1901. Serial No. 66,194. (No model.)

Claim.—1. The combination with a hub having spoke-flanges spaced inwardly from the ends thereof, the hub adjacent to the outer face of one of the flanges being threaded, a sprocket secured onto said threads and lying against the flange, said sprocket having a rabbet at its inner edge, a clamping-rod engaged with the threads of the hub and disposed in the rabbet to clamp the sprocket, said sprocket having also an annular flange on its outer face, and an axle disposed in the hub and having bearings between it and the hub, said axle having a cap at one end and disposed over the end of the hub and having a rotating flange disposed against the outer face of the sprocket and the inner face of its flange.

2. The combination with a hub having spoke-flanges, one of said flanges having studs on its outer face, of a sprocket engaged with the hub and having recesses which receive the studs, an axle disposed through the hub and having a cap including one end of the hub and having a flange at its edge lying against the sprocket, said cap being adapted to receive a fork side, a clamping-rod engaged with the cap for clamping

the fork side against the flange, and bearings between the axle and hub, one of said bearings lying within the enclosure of the cap.

3. The combination with a hub of an axle passed therethrough and having a cap including one end of the hub, said cap being adapted to receive a fork side and having means for clamping it thereon, said cap also having a bearing inserted thereby, a sleeve disposed on the axle and terminating short of the end thereof opposite to the cap, a bearing between the hub and sleeve, and a clamping-rod on the axle beyond the sleeve and adapted to clamp a fork side against the end of the sleeve.

698,942. SIGNAL-STATION. JOHN W. HARRISON, Detroit, Mich. Filed Mar. 12, 1901. Serial No. 66,902. (No model.)

Claim.—1. In combination with a station-building having two entrances, and a floor in two sections, each of which is independently movable, a casing on each floor-section arranged to enclose a person within the station to the section to which he first enters, and a signaling apparatus connected with each of said sections and adapted to be actuated by the movement thereof, one of said signaling apparatus being adapted to signal a train coming in one direction, and the other to signal a train coming in the other direction.

2. In combination with a station-building provided with a floor in two sections, each of which is independently movable, a signaling apparatus connected with each of said sections and adapted to be actuated by the movement of the section with which it is connected, one of said signaling apparatus being adapted to signal a train coming in one direction, and the other to signal a train coming in the other direction.

3. In combination with a station-building provided with two entrances and a floor in two sections arranged so that a person entering by one entrance shall step upon one section and another person entering by the other entrance shall step upon the other section and actuate it, a signaling apparatus connected with each of said sections and adapted to be actuated by the movement thereof, one of said signaling apparatus being adapted to signal a train coming in one direction, and the other to signal a train coming in the other direction.

4. In combination with a station-building provided with a floor in two sections, each of which is independently movable, a signal upon each end of said building facing toward the direction from which the trains come, and a mechanism connected with each of said signals and with each of said sections such that the movement of one of said sections shall operate one of said signals and the movement of the other section shall operate the other of said signals.

698,943. UTENSIL FOR DISPLAY OF GOODS. CLARENCE E. HARRIS, Pittsburg, Pa., assignor to H. J. Harris Company, Allegheny, Pa., a Partnership. Filed May 24, 1901. Serial No. 61,708. (No model.)

Claim.—1. A portable stand for the display of articles of food, &c., having in combination a water-containing vessel, a vessel or receptacle having two or more compartments and secured in position within the

water vessel, independent covers for said compartments, a carrying-handle and a lamp a seat secured to the outer vessel, substantially as set forth.

2. A portable stand for the display of articles of food, &c., having in combination a water-containing vessel, a vessel or receptacle secured within and forming a tight joint with the water vessel and having two or more compartments, independent covers for said compartments, a carrying-handle secured to the inner vessel, a filling-spout connected to the water vessel and a lamp a seat secured to the outer vessel, substantially as set forth.

3. A portable stand for the display of articles of food, &c., having in combination a water-containing vessel, a vessel or receptacle detachably secured within and sealing the water vessel and having two or more compartments, independent covers for said compartments, a carrying-handle secured to the inner vessel and a lamp a seat secured to the outer vessel, substantially as set forth.

4. A portable stand for the display of articles of food, &c., having in combination a water vessel having a filling-spout, a vessel or stand secured in and sealing the water vessel, one or more partitions arranged transversely of the inner vessel, covers hinged to said partitions and provided along their hinged edges with flanges adapted to bear against the partitions when the covers are closed, substantially as set forth.

698,944. ROLLER-BEARING. FREDERICK HENNINGSEN and EMERALD HENNINGSEN, Baltimore, Md. Filed May 27, 1901. Serial No. 66,964. (No model.)

Claim.—1. In a roller-bearing, the combination with an axle, of a hub, and two independent sets of conical rolls surrounding said axle, one set being arranged at each end of the hub and both sets of rolls being inclined in the same direction.

2. In a roller-bearing, the combination with an axle, of a sleeve surrounding said axle, a set of conical rolls arranged at one end of said sleeve between said axle and sleeve, and a set of conical rolls at the other end of said sleeve and surrounding said sleeve.

3. In a roller-bearing, the combination with an axle, of a sleeve surrounding said axle, a set of conical rolls arranged between said axle and sleeve at the inner end thereof, and a set of conical rolls arranged outside of said sleeve at the outer end thereof.

4. In a roller-bearing, the combination with an axle, of a sleeve surrounding said axle, a set of conical rolls arranged at one end of said sleeve between said axle and sleeve, a removable cap carried by said axle at the other end of said sleeve and surrounding the same, and a set of conical rolls between said removable cap and sleeve.

5. In a roller-bearing, the combination with an axle, of a sleeve surrounding said axle, and having an enlarged portion at one end of said sleeve, a set of conical rolls arranged within said enlarged portion and around said axle, a second set of conical rolls surrounding the opposite end of said sleeve, and a removable cap surrounding said second set of rolls.

698,945. BRACKET. WILLIAM E. HENRY, New Britain, Conn., assignor to P. & F. Curtis, New Britain, Conn., a Corporation of Connecticut. Filed Jan. 4, 1902. Serial No. 66,090. (No model.)

Claim.—1. A bracket comprising a top and back, and a web connecting said top and back, said web being of a single thickness of metal, said top and back being of a double thickness of metal, said parts being connected integrally.

2. A bracket comprising a web, an extension above said web and an extension below said web, each of said extensions being integral with said web portion and doubled upon themselves twice to produce the top

of the bracket and a back for the bracket, both the top and back being of double thickness.

698,946. CURRYCOMB. CHARLES E. HENNINGSEN, Larry, Va. Filed Mar. 4, 1902. Serial No. 66,908. (No model.)

Claim.—1. A currycomb made in two sections hinged together in the middle upon an axle at right angles to the rows of teeth, substantially as described.

2. A currycomb made in two sections hinged together in the middle upon an axle at right angles to the rows of teeth, and springs for restoring these wings to a normal flat plane after having been deflected substantially as described.

3. A currycomb made in two sections hinged together in the middle upon an axle at right angles to the rows of teeth, springs for restoring these wings to a normal flat plane after having been deflected, and a loop or receiver for the head arranged upon the back of the currycomb to give a purchase for compressing the wings inwardly against the springs substantially as described.

4. A currycomb made in two sections hinged together in the middle upon an axle at right angles to the rows of teeth, combined with two cleaner-grids arranged to turn about the same axis substantially as described.

5. A currycomb made in two sections hinged together in the middle line upon an axle at right angles to the rows of teeth, each of said sections having an attached set of cleaner-grids arranged to lie beneath the teeth of the opposite section substantially as described.

6. A currycomb made in two sections hinged together in the middle upon an axle at right angles to the rows of teeth, and two sets of cleaner-grids attached, one to each currycomb-section, and wound about the axle so as to act also as springs for controlling the movement of the currycomb-sections substantially as described.

7. A currycomb made in two sections hinged together in the middle upon an axle at right angles to the rows of teeth, two sets of cleaner-grids attached to the said sections and arranged to turn about the same axle, and thumb-pieces attached to the hinged sections to permit their convenient deflection in cleaning substantially as described.

698,947. JOURNAL BEARING. HENNINGSEN E. HENRY, Baltimore, Md. Filed Dec. 18, 1901. Serial No. 66,000. (No model.)

Claim.—1. A bay or wedge for a bar-axle bearing having its under surface formed with a seat and a bearing-plate of a different kind or quality of metal rigidly fixed in said seat and having its under surface formed with a spherical concavity adapted to receive a convex on the top of the axle-rod.

2. A bar-axle bearing, comprising a beam convex upon its upper surface in combination with a bay or wedge having its under surface formed with a concaved seat and a convex-concave bearing-plate of a different kind or quality of metal rigidly held in said seat, the under surface of said bearing-plate receiving the convex on the top of said beam.

3. A bar-axle bearing, comprising a journal-rod convex upon its upper surface in combination with a bay or wedge formed with a concaved seat or recess and a convex-concave bearing-plate of a different kind or quality of metal rigidly fixed in said seat or recess, the edges of said bearing-plate being engaged by the overhanging portion of the bay or wedge.

4. A bay or wedge for a bar-axle bearing formed of iron and having its under side provided with a concaved recess, and a convex-concave bearing-plate of a different kind or quality of metal having a polished lower surface and rigidly fixed in the seat of said bay or wedge.

698,948. APPARATUS FOR MAKING PAILS FROM PULP. ALBERT D. REYL, Saginaw, Mich. Filed June 21, 1901. Serial No. 68,646. (No model.)

Claim.—1. In an apparatus for manufacturing pails and other vessels from pulp, the combination of an inner and outer former, and means for imparting a rotary movement to one of said formers.

2. In an apparatus for pressing pulp and other vessels from pulp, the combination of inner and outer formers, the outer former being provided with a slit-metal lining or covering, and means for imparting a rotary movement to said outer former.

3. In an apparatus for pressing pulp and other vessels from pulp, the combination of inner and outer mold members or formers, said outer member being provided with a slit-metal lining or covering.

4. In an apparatus for pressing pulp and other vessels from pulp, an inside former or member provided with a slit-metal covering or lining, an outside member and means for rotating said members.

5. The combination of an inner and an outer mold member or former, means for imparting a rotary movement to one of said formers, means for permitting the introduction of pulp into the space between said formers, a valve for controlling the flow of pulp to said space, and mechanism for operating said valve.

6. The combination of a casing, a piston therein, an outer former supported by said piston, an inner former of lesser diameter, a casing upon which said inner former is supported, a cushioning device for regulating the descent of said inner former and means for raising said inner former and the pressed pulp, whereby the latter can be readily removed.

7. The combination of an outer casing, a piston therein, racks on the inside of said piston, toothed segments adapted to mesh with said racks, an inner and an outer former and device operated by said segments and racks for completing the formation of the pail.

8. In an apparatus for making pails, an inner mold, means for locking the latter in its lower position, an outer mold, means for raising the latter, a plurality of pivotal heads, a plate adapted to mesh with said heads, a series of slides located above the inner or upper mold, and means for raising the latter prior to disengaging the pulp therefrom.

9. In an apparatus for making pails, an inner mold adapted to receive pulp, a valve opening therein, a lower or outer mold, a piston supporting the latter, a casing supporting said inner mold, a cushioning device for the upper part of said casing, and means for locking said casing in its upper and lower positions.

10. In an apparatus for making pails, a cylinder, a piston therein, means for raising said piston, an outer mold carried by said piston, a plate located transversely of said piston for catching water drained from the pulp, a stationary pipe extending lengthwise of said cylinder, segments on said pipe, racks carried by said piston and meshing with said segments,

a plunger in said pipe, a plate carried by said plunger, a series of pivotal heads surrounding said plate, means for moving said heads laterally during compression of the pulp, an inner mold, a casing supporting the latter, means for raising said casing, and means for locking the latter in its upper and lower positions.

698,949. STREET-SWEEPER. WILLIAM HENRY, Boston, Mass. Filed Dec. 14, 1901. Serial No. 68,645. (No model.)

Claim.—1. A street-sweeper, comprising in combination with the truck, the shaft and driving-wheel, a swinging beam pivotedly mounted on the truck, a rotary sweeper journaled at the end of said beam, and having geared connection with the driving-shaft, a standard on said swinging beam, and counterbalanced pivoted lever mounted on said standard, and designed to allow the brushes to conform to a pavement, as set forth.

2. A street-sweeper, comprising in combination with the truck, the driving-shaft and wheels, a swinging beam pivoted to the truck, a hollow shaft journaled at the end of said beam and having geared connection with the driving-shaft for rotating same, plates carried by said shaft, pivotal brush-arms mounted between said plates, a solid shaft passing through said hollow shaft, a stationary cam horizontally mounted on the lower end of said solid shaft, integral pins on said brush-arms which contact with the periphery of said cam, and a counterbalanced lever mounted on said swinging beam and having pivotal connection with said solid shaft, as set forth.

3. In a street-sweeper, a truck-driving axle and wheels, a swinging beam pivotedly connected to said truck, a hollow shaft carried at the free swinging end of said beam, a ratchet-wheel rotating with said hollow shaft and geared connection between the same and the driving-axle, recessed plates mounted upon and rotating with said hollow shaft, a series of brush-arms held between said plates adapted to lift vertically, a stationary cam-wheel, against which each arm is adapted to contact and be raised thereby, as it rotates, a shaft mounted within the hollow shaft, and to which inner shaft said cam-wheel is secured, a weighted lever hinged on a standard rising from the swinging beam and pivoted to the upper end of said cam-wheel-carrying shaft and guide mechanism for regulating the distance at which it is desired to have the rotary brush held with relation to a work.

4. In combination with the truck, the driving-axle and wheels, a swinging beam pivoted to the truck, a vertically-rotating shaft mounted on the outer end of the swinging beam, brushes carried by said shaft, geared connections with the main axle, for driving said shaft, a guide-wheel and pivotal link connections between same and the frame, and with the swinging beam, and a coil-spring connected at one end to the truck, and its other end to said beam as shown and described.

698,950. RAILWAY-SWITCH. NORMAN E. HILL, East Hampton, Conn. Filed Dec. 12, 1901. Serial No. 68,662. (No model.)

Claim.—1. In a bicycle-bell, the combination with a gong, of a striker, a loosely-mounted balance-wheel by which the striker is carried, and means for imparting an initial rotary impulse to the balance-wheel, including a coupling device which permits the balance-wheel to continue to rotate independently of the said means after it has once been started rotating.

2. In a bell, the combination with a gong, of a striker, a loosely-mounted balance-wheel upon which the striker is mounted, a piston carried by the balance-wheel, a loose gear-wheel meshing into the said piston,

a ratchet-wheel, a pawl carried by the loose gear-wheel and meshing with the said ratchet-wheel, and means for positively rotating the ratchet-wheel, whereby its rotary movement is communicated through the pawl to the gear-wheel, and hence to the balance-wheel, which, when once started in rotation, keeps on rotating until its inertia is spent.

3. In a bicycle-bell, the combination with a gong, of a striker, a loosely-mounted balance-wheel carrying the said striker, a piston carried by the said balance-wheel, a loose gear-wheel meshing into the said piston, a ratchet-wheel, a pawl for coupling the said gear-wheel and the ratchet-wheel together, a shaft upon which the ratchet-wheel is mounted, a piston carried by the said shaft, and a rack meshing into the said piston last mentioned.

4. In a bicycle-bell, the combination with a central frame or body, of two studs connected therewith, gongs applied to the said studs, balance-wheels loosely mounted on the respective studs on opposite sides of the said frame, an operating-lever connected with the frame, and operating mechanism between the said lever and balance-wheels, whereby they are given an initial rotary impulse and then emancipated from the said operating-lever, and left free to spend their initial rotary impulse.

698,951. BUTYROL-BELL. NORMAN E. HILL, East Hampton, Conn. Filed Mar. 24, 1902. Serial No. 68,761. (No model.)

Claim.—1. In a bicycle-bell, the combination with a gong, of a striker, a balance-wheel by which the striker is carried, a pawl carried by the balance-wheel, a ratchet-wheel engaged by the said pawl and having its axis co-axial with the axis of the balance-wheel, and means for positively rotating the said ratchet-wheel which is free to turn independently of the balance-wheel in the opposite direction from the direction in which the same turns.

2. In a bicycle-bell, the combination with a gong, of a striker therefor, a balance-wheel by which the striker is carried, a pawl mounted upon the balance-wheel, a ratchet-wheel engaged by the said pawl, a hub on which the balance-wheel is loosely mounted and to which the said ratchet-wheel is fixed, a piston also connected with the said hub and ratchet-wheel which latter operates through the pawl to rotate the balance-wheel which continues to rotate after the ratchet-wheel has been operated and until its inertia is spent.

3. In a bell, the combination with a gong, of a striker, a balance-wheel carrying the said striker, a pawl also carried by the said balance-wheel, a ratchet-wheel meshing with the said pawl, a hub passing through the balance-wheel which is free to turn upon it and upon the outer end of which the said ratchet-wheel is fixed, a piston located upon the inner end of the said hub, a post upon which the said hub rotates, a wheel meshing into the said piston, a piston carried by the said wheel, and a spring-controlled operating-lever formed with a rack engaging with the piston last mentioned, whereby the balance-wheel is positively actuated in rapid rotation by means of the said lever and allowed to continue its rotation, until its inertia is spent, by the dragging of the said pawl over the said ratchet-wheel.

698,952. RAILWAY-SWITCH. WILLIAM W. BUTTERFIELD and FRANK W. FOWLER, West Lafayette, Ind., assignors to Electric and Steam Railway Supply Co., Lafayette, Ind. Filed Aug. 12, 1901. Serial No. 71,817. (No model.)

Claim.—1. In a railway-switch, the combination with vertically-movable switch-points, rack-shafts for elevating and depressing said switch-points, cranks upon the ends of said rack-shafts, and a rod connecting said cranks; of a rod connected to one of said cranks, and a link for preventing the movement of said cranks except through the reciprocation of said rod, substantially as described.

2. In a railway-switch, the combination with vertically-movable switch-points, and rack-shafts supporting said switch-points; of a reciprocating rod connected to said rack-shafts, a lag upon said rod, and levers or dogs adapted to engage said lag, substantially as described.

3. In a railway-switch, the combination with vertically-movable switch-points, rack-shafts for elevating and depressing said switch-points, and cranks upon the ends of said rack-shafts; of a rod connected to one

of the cranks upon said rack-shafts, a lag carried by said rod, and levers or dogs adapted to engage said lag, substantially as described.

4. In a railway-switch, the combination with vertically-movable switch-points, rack-shafts for elevating and depressing said switch-points, cranks upon the ends of said rack-shafts, and a rod connecting said cranks together; of a rod having an elongated slot adapted to engage one of said cranks, a lag carried by said rod, and levers or dogs adapted to engage said lag, and lock the switch, substantially as described.

5. In a railway-switch, the combination with vertically-movable switch-points, rack-shafts adapted to elevate and depress said switch-points, cranks upon the ends of said rack-shafts, and chains supporting the said racks, in which said rack-shafts are journaled; of a rod connected to said cranks, a lag carried by said rod and levers or dogs supported upon one of said chains, adapted to engage said lag when the switch is either open or closed, substantially as described.

6. In a railway-switch, the combination with vertically-movable switch-points, rack-shafts, lags carried by said rack-shafts for elevating and depressing said switch-points, and cranks upon said rack-shafts, connected together by a rod; of a rod connected to one of said cranks; a pair of rollers or stops secured upon said rod, and a crank adapted to reciprocate said rod through said rollers or stops, substantially as described.

7. In a railway-switch, the combination with the switch-points, and means for raising and lowering said switch-points; of a rod connected to said mechanism, a rack-shaft carrying an operating-lever, rollers upon said rod, and a crank-arm upon said rack-shaft, adapted to reciprocate said rod through said rollers, substantially as described.

8. In a railway-switch, the combination with the switch-points, and means for raising and lowering said switch-points; of a rod connected to said mechanism, a rack-shaft carrying an operating-lever, rollers upon said rod, a crank-arm upon said rack-shaft, adapted to reciprocate said rod through said rollers, and means for locking said rack-shaft against rotation, substantially as described.

9. In a railway-switch, the combination with switch-points, and means including a rod, for operating said switch-points; of a rack-shaft supported in bearings between the ties, an operating-lever carried by said rack-shaft, a crank-arm upon the opposite end of said rack-shaft, dogs upon said rod with which said crank-arm is adapted to engage, a slot in said bearing, and biased plates adapted to cover said slot upon each side of said operating-lever, locking the same against operation, substantially as described.

10. In a railway-switch, the combination with switch-points, and mechanism including a rod for operating said switch-points; of a double crank connected to one end of said rod, a rod connecting said double crank to an indicator, and an alarm or other device adapted to sound when the switch is opened or closed, substantially as described.

11. In a railway-switch, the combination with the switch-points, and mechanism including a rod for operating said switch-points; of a double crank connected to one end of said rod, a rod connecting said double crank to a second double crank, adapted to be located in a station,

and an operating-lever adapted to engage steps upon one of said wires, to reciprocate said rod, substantially as described.

12. In a railway-switch, the combination with the switch-points, and mechanism including a rod for operating said switch-points; of a double crank connected to one end of said rod, wire connecting said double crank to a second double crank, adapted to be located in a station, an operating-lever adapted to engage steps upon one of said wires, to reciprocate said rod, and an indicator carried by said double crank, substantially as described.

13. In a railway-switch, the combination with vertically-movable switch-points, and rock-shafts supporting said switch-points; of a reciprocating rod connected to said rock-shafts, a lag upon said rod, latches or dogs adapted to engage said lag, and steps adapted to limit the movement of said latches, substantially as described.

14. In a railway-switch, the combination with vertically-movable switch-points, and rock-shafts supporting said switch-points, adapted to elevate and depress said switch-points; of a reciprocating rod connected to said rock-shafts, a lag upon said rod, latches or dogs adapted to engage said lag, a spring tending to draw said latches together, and steps adapted to limit the movement of said latches, substantially as described.

15. In a railway-switch, the combination with the switch-points, and mechanism including a rod for operating said switch-points; of a double crank connected to one end of said rod, wire connecting said double crank to a second double crank, adapted to be located in a station, an operating-lever adapted to engage steps upon one of said wires, to reciprocate said rod, and means for locking said operating-lever against operation, substantially as described.

16. In a railway-switch, the combination with the switch-points, and mechanism including a rod for operating said switch-points; of a double crank connected to one end of said rod, wire connecting said double crank to a second double crank, adapted to be located in a station, an operating-lever adapted to engage steps upon one of said wires, to reciprocate said rod, and means for locking said operating-lever against operation, substantially as described.

17. A switch-point for railway-switches, comprising a rail having its free end bent at an angle, and the gage side of this bent portion cut away to form a straight line with the remaining portion of the rail, deep enough to allow the wheel-flanges to pass.

18. A switch-point for railway-switches, comprising a rail having narrow flanges at its pivoted end, these flanges disappearing at the free end of the switch-point, and the free end of the switch-point being composed of a solid tapering rectangular section, said rectangular portion being bent off from the remaining portion of the switch at an angle as to fit against the side of the adjacent main rail, the gage side of the bent rectangular portion of the rail being cut away in a straight line with the gage side of the remaining portion of the rail, the portion below this cut-away portion being left intact.

698,958. GARDNER. GEORGE W. HARRIS, Broken Bow, Neb., assignor of one-third to J. R. Dean, Broken Bow, Neb. Filed Sept. 26, 1901. Serial No. 78,004. (No model.)

Claim.—In a carburetor, a tank for liquid hydrocarbon, a service-pipe leading therefrom at an elevated point, in combination with means to compress air, and a pipe to discharge the compressed air into said tank in the body of the liquid hydrocarbon therein, said pipe having oppositely-disposed jet-tips of reduced capacity to discharge compressed air in jets which impinge against each other and in the liquid hydrocarbon, for the purpose set forth, substantially as described.

698,954. CAR-FENDER. CLARENCE F. BAKER, Milwaukee, Wis. Filed Oct. 21, 1901. Serial No. 88,097. (No model.)

Claim.—1. In a car-fender, the combination with a suitable frame comprising longitudinal and transverse strips, and having friction-wheels secured thereto and adapted to travel upon the tracks, of a front transverse shaft having a series of independent separate rollers mounted thereon, and carrying wheels fast on said shaft and connected to said friction-wheels so as to revolve in the opposite direction to the revolution of said friction-wheels, and the said front shaft being adapted, by its backward revolution, to carry objects with which it comes in contact up and over upon the frame of the fender, the said rollers on the front shaft being separated by, and rising to a higher plane than, the front ends of the said longitudinal strips.

2. In a car-fender, the combination with a suitable frame comprising longitudinal and transverse strips, and having friction-wheels secured thereto and adapted to travel upon the tracks, of a front transverse shaft, wheels fast on said shaft and supported above said tracks, and cross-geared to said friction-wheels so as to revolve in opposite directions thereto, and a series of independent separate rollers of yielding material mounted on the said front transverse shaft, the said longitudinal strips of the fender-frame alternating with the said rollers, and the front ends of said strips being curved around the said front shaft.

3. The combination with a car-platform provided with hangers on its upper side, and an opening therethrough in front of said hangers, of a fender-frame, having side bars hinged to said hangers, and projecting in front of said platform, and having their front ends guided by a transverse shaft pivotally secured thereto, said shaft carrying wheels fast on its outer ends; a rear transverse shaft, pivotally secured to said side bars, and carrying friction-wheels adapted to travel on the tracks, and geared to the wheels on the ends of the said front transverse shaft, the wheels on the two transverse shafts being adapted to revolve in opposite directions; a series of independent separate rollers on the front transverse shaft; and a rod, hinged to the fender-frame and passing through the said opening in the platform, said rod being provided with a catch for supporting the fender-frame in a raised position when not in use.

698,955. BRIDGE FOR MUSICAL INSTRUMENTS. EDWARD E. JAMESON, London, England. Filed Nov. 28, 1901. Serial No. 83,602. (No model.)

Claim.—1. A bridge for supporting the strings of a musical instrument composed of a string-support resting on a bell-mouthed pier.

2. A bridge for the strings of a musical instrument having a plurality of bell-mouthed supports, and a tie-bar of low-conductivity connecting and supporting said bell-mouthed supports.

3. A bridge for the strings of a musical instrument composed of a plurality of tie-bars of low conductivity of vibration affixed to a series of hollow bell-mouthed feet supporting the strings of the said instrument.

4. In a stringed musical instrument a bridge supported upon a bell-shaped base including between its walls and the vibratory surface of the instrument a volume of air.

5. In a musical instrument provided with vibratory strings, a bridge composed of a string-support, a connecting-neck, and a bell-shaped hollow support.

6. In a stringed-musical-instrument bridge a plurality of string-supporting supports, connecting-necks and bell-shaped hollow air-including

feet and a tie-rod connecting said bell-shaped feet at adjusted distance apart.

7. Is a stringed-musical-instrument bridge the combination of a plurality of string-retainers, a corresponding number of connecting-necks and attached bell-shaped hollow feet and a plurality of tie-rods holding said feet in adjusted position.

698,956. GARMENT-TURNING APPARATUS. WILLIAM G. JARVIS, Delaware, Ohio. Filed Dec. 26, 1901. Serial No. 87,328. (No model.)

Claim.—1. A machine of the class described, comprising a tubular member for supporting the article, a plunger mounted to swing and to reciprocate and adapted when reciprocated to pass into the tubular member, and means for swinging the plunger horizontally when it moves into its uppermost position, as set forth.

2. A machine of the class described, comprising a plurality of tubular members in alignment with each other and spaced apart, plungers adapted to be passed into the said members, as set forth.

3. A machine of the class described, comprising a table, a plurality of tubular members supported vertically on said table, a corresponding number of plungers for engaging the tubular members, a plunger-frame carrying the plungers and provided with side arms mounted to slide in bearings carried by the table, cross-rods connecting the side arms of the frame at top and bottom, springs connected with the bottom cross-rod and screw-rods carrying in the table and connected with said springs for adjusting the tension of the table, as set forth.

4. A machine of the class described, comprising a plurality of tubular members in alignment with each other and spaced apart to receive the reversed fingers of a glove or like article, a corresponding number of plungers adapted to be passed into the said members to continuously reverse the fingers of the glove or like article, a cross-head carrying the said plungers, means for moving the cross-head up and down to engage the plungers with the tubular members, and means for turning the cross-head to swing the plungers into the rearward position at the time the cross-head is in the uppermost position, as set forth.

5. A machine of the class described, comprising a fixed socket, tubular members removably secured therein, plungers for engaging the said tubular members, a cross-head removably carrying the said plungers, a plunger-frame in which the cross-head is mounted to swing, the said plunger-frame being mounted to reciprocate, means for imparting reciprocating motion to the said plunger-frame and means for swinging the cross-head, as set forth.

6. A machine of the class described, comprising a fixed socket, tubular members removably secured therein, plungers for engaging the said

tubular members, a cross-head removably carrying the said plungers, a plunger-frame in which the cross-head is mounted to swing, the said plunger-frame being mounted to reciprocate, means for imparting reciprocating motion to the said plunger-frame, and a device for imparting a rearward-swinging motion to the said cross-head and plungers at the time the plunger-frame moves into the uppermost position, as set forth.

7. A machine of the class described, comprising a tubular member, a plunger for engaging the tubular member, a cross-head carrying the plunger, a plunger-frame mounted to reciprocate and in which the cross-head is mounted to swing, means for reciprocating the plunger-frame, and means for swinging the cross-head, comprising cam-arms pivoted to a fixed support and provided with cam-grooves engaged by friction-rollers on the plunger-frame, and a connection between said cam-arms and end of said plungers, as set forth.

8. A machine of the class described, comprising a table, a plurality of tubular members in alignment with each other and spaced apart, plungers adapted to be passed into the said members, a cross-head carrying the said plungers, a plunger-frame in which the cross-head is mounted to swing, means for swinging the cross-head, springs for normally holding the plunger-frame in the uppermost position, and a link connecting the lower part of the plunger-frame with a treadle, as set forth.

9. A machine of the class described, comprising a table, tubular members carried thereby, plungers for engaging the tubular members, a cross-head carrying the said plungers, a plunger-frame mounted to reciprocate and in which the cross-head is mounted to swing, means for reciprocating the plunger-frame, cam-arms pivoted at their lower ends to a fixed support and provided with cam-grooves engaged by friction-rollers on the side of the plunger-frame, a shaft journaled in the upper ends of the cam-arms, a link carried by said shaft, and pairs of friction-rollers held on said link and engaging end of said plungers, as set forth.

698,957. APPARATUS FOR COUPLING OR UNCOUPLING RAILWAY ROLLING-STOCK. JAMES FENNER, CHART, England. Filed July 12, 1901. Serial No. 88,970. (No model.)

Claim.—1. Apparatus for coupling railway-cars comprising a pivoted chain-linker, a slotted guide in which it is mounted, projections on the upper part of the linker, and an operating-handle whereby, on the continued movement of the handle the links are first raised, the projections are forced against the car-body and the pivoted chain-linker and chain are forced outward in the slotted guide.

2. Apparatus for coupling railway-cars comprising a pivoted chain-linker, a slotted guide in which it is mounted, projections on the upper part of the linker, and an operating-handle whereby, on the continued movement of the handle the links are first raised, the projections are forced against the car-body and the pivoted chain-linker and chain are forced outward in the slotted guide, in combination with a projection on the lower side of the linker adapted to be acted on by the back of the approaching car, to throw the linker backward in its slotted guide and drop the extended link over the back, substantially as described.

3. Apparatus for coupling railway-cars comprising a pivoted linker, an operating-shaft for the linker, a slotted guide therefor on each side of the car and a recessed outer end to the slides and means for first raising the linker and then advancing it on the rotation of the shaft so that the shaft occupies a position in the forward end of the guide and is retained there by the recess, as set forth for the purpose described.

4. Apparatus for coupling railway-cars comprising a pivoted linker, an operating-shaft for the linker, a slotted guide therefor on each side of the car and a recessed outer end to the slides and means for first raising the linker and then advancing it on the rotation of the shaft so that the shaft occupies a position in the forward end of the guide and is retained there by the recess, in combination with a projection on the under side of the linker adapted to be acted on by the back of an approaching car to throw the linker back out of the recess and permit the linker to fall onto the back, substantially as described.

698,958. INTELLIGENT APPARATUS. BENJA JAMESON, Peabody, Cal. Filed Aug. 29, 1901. Serial No. 78,005. (No model.)

Claim.—1. In an apparatus for distillation, the combination with a condenser, of a pipe extending out laterally therefrom, means for detachably connecting one end of the pipe to the condenser, and an arm detachably connecting the overhanging portion of the pipe to the condenser.

2. In an apparatus for distillation, the combination with a condenser having an ear, of a pipe extending out laterally therefrom, means for detachably connecting one end of the pipe to the condenser, and an arm connected to the overhanging portion of the pipe and provided with a projection which is adapted for engagement with the ear.

3. In an apparatus for distillation, the combination with a condenser, of a pipe extending out laterally therefrom, and a pivoted ball detachably connecting the overhanging portion of the pipe to the condenser.

4. In an apparatus for distillation, the combination with a condenser, of a pipe adapted for connection thereto, a pin on the pipe, and a ball pivoted to the condenser and adapted to engage the pin.

5. In an apparatus for distillation, the combination with a condenser, of a pipe extending out laterally therefrom, a ball pivoted to the condenser, a pin on the pipe with which the ball is adapted to engage, and an arm on the overhanging portion of the pipe adapted for detachable engagement with the condenser.

6. In an apparatus for distillation, the combination with a condenser, of a pipe connected thereto and extending out laterally therefrom, and a distilling vessel suspended in mid-air from the overhanging end of the pipe.

7. The combination with a tea-bottle, of a condenser, an overhanging pipe connected to the condenser and having a collar on its overhanging portion, turn-buttons on the collar having hooks adapted to engage the margin of the opening in the bottle, an arm connecting the collar with the condenser, and a stopper for the spout of the tea-bottle which is attached to the collar.

698,959. HEBEL-LIFT FOR BOOTS OR SHOES. James J. Jones, New York, N.Y. Filed Mar. 27, 1900. Serial No. 10,242. (No model.)

Claim.—1. As a new article of manufacture, a composite heel-lift for boots and shoes, comprising a block or form of rubber having a continuous wall completely inclosing an open center, the inner surface of said wall being of irregular or offset outline, and a filling-block of a material different from and of corresponding thickness with the block of rubber, the edge of the filling-block being of irregular outline and fitting the open center within the wall of the block of rubber and extending with the wall thereof, substantially as set forth.

2. As a new article of manufacture, a composite heel-lift for boots and shoes, comprising a block of rubber having a wall completely inclosing an open center, the inner surface of said wall being provided with an undercut recess, and a filling-block of leather corresponding in thickness with the said rubber block, fitting the open center thereof and having a peripheral rib which fits the inner wall of the rubber block, substantially as specified.

698,960. PULVERIZER. James R. Jones, Jackson, Miss. Filed Aug. 27, 1901. Serial No. 78,027. (No model.)

Claim.—1. In agricultural implements, a pulverizer, consisting of hub-sections mounted to revolve upon a shaft, each hub-section comprising a hub and spaced segmental members attached to the outer face of the hub, means, substantially as described, for connecting the hub-sections, and a paddle carried by the said shaft and extending within the arched portion of the pulverizer, for the purpose set forth.

2. In agricultural implements, a pulverizer consisting of opposing hub-sections, each hub-section comprising a hub and segmental members connected with the outer face of the hub, an arched section intervening between the hub-sections, the arched section having openings therein, a fixed shaft on which the hub-sections are mounted to turn, and a paddle carried by the said shaft and extending within the arched portion of the pulverizer, for the purpose set forth.

3. In agricultural implements, the combination, with opposing hub-sections, each hub-section comprising a hub and segmental plates attached to the outer face of the hub, spaces intervening between the opposing ends of the segmental plates, means, substantially as described, for connecting the hub-sections, and a fixed shaft on which the hub-sections are mounted to turn, of plates which enter the spaces between the segmental members of the hub-sections, each plate being provided with an arched member at right angles to the plate, which arched members are located between the opposing edges of the hub-sections, and a paddle carried to the said shaft, entering the arched members of the plates and conforming to the contour of the said arched members, as and for the purpose specified.

4. In agricultural implements, a pulverizer consisting of opposing hub-sections, each section comprising a hub, and segmental members secured to the outer face of the hub, spaces intervening between the opposing ends of the said segmental members, a fixed shaft upon which the hub-sections turn, plates closing the periphery of the outer ends of the hub-sections, fastening devices passed through the closing-plates and through the segmental members of the hub-sections, longitudinal plates which enter and fill the openings intervening between the segmental members of the hub-sections, each longitudinal plate being provided with an arched central member, extending transversely of the plate, the arched members of the longitudinal plates being located between the hub-sections, the arched members of the longitudinal plates being as constructed that spaces intervene between them, which spaces are in communication with the interior of the pulverizer, a fixed shaft on which the hub-sections revolve, and a paddle carried to the said shaft, extending and loosely fitting in the arched members of the longitudinal plates, for the purpose set forth.

698,961. STRAINER. William Jones, London, Eng. Filed Sept. 25, 1901. Serial No. 76,174. (No model.)

Claim.—1. The combination with a funnel, of a hollow strainer therein having an imperforate upper portion, a perforated diaphragm between the perforate and imperforate portions of the strainer and a tube passing through said diaphragm and connecting the space above it with the spout of the funnel and making a tight connection with said spout.

2. The combination with a funnel, of a hollow strainer therein having an imperforate upper portion, a perforated diaphragm between the perforate and imperforate portions of the strainer, a tube passing through said diaphragm and connecting the space above it with the spout of the funnel and a stopper surrounding said tube for making a tight joint with the spout.

3. The combination with a funnel of a conical strainer therein having an imperforate cap on its upper end, a perforated diaphragm below said cap and a tube passing through said diaphragm and connecting the space above it with the spout of the funnel and making a tight connection therewith.

4. The combination with a funnel of a conical strainer therein having an arched or convex imperforate cap, a perforated diaphragm at the top of the conical portion of the strainer and below said cap, a tube leading from said diaphragm and connecting the space above it with the spout of the funnel and a stopper surrounding said tube for forming a tight joint with the spout.

5. The combination with a funnel of a conical strainer therein having an arched or convex imperforate cap, a perforated diaphragm between the conical portion of the strainer and the cap forming an upper and a lower chamber, a tube leading from the upper chamber through the diaphragm and the lower chamber and into the spout of the funnel, a stopper surrounding said tube for forming a tight joint with the spout and filtering material filling the lower chamber.

698,962. ORIENTING-MACHINE. GEORGE JULIAN, Boston, Mass. Assignor, by mesne assignments, to Julian Manufacturing Company, Boston, Mass., a Corporation. Filed Mar. 23, 1901. Serial No. 69,190. (No model.)

Claim.—1. A cementing-machine comprising a cement-applying roll having pockets in its periphery, a bed-roll which supports the work under the applying-roll, a cement-preparator adapted to hold a body of cement against one side of the applying-roll above its cement-applying portion, a wiper which bears against the periphery of the applying-roll between the body of cement and the said applying portion, and means for adjusting said wiper relatively to the periphery of the applying-roll.

2. A cementing-machine comprising a cement-applying roll having pockets in its periphery, a bed-roll which supports the work under the applying-roll, a cement-preparator having end portions bearing against the ends of the applying-roll, and a bottom portion or wiper extending along the periphery of the applying-roll and in wiping or rubbing contact therewith, between the body of cement and the said applying portion.

3. A cementing-machine comprising a cement-applying roll having pockets in its periphery, a bed-roll which supports the work under the applying-roll and is pressed yieldingly toward the applying-roll, a cement-preparator having end portions bearing against the ends of the applying-roll and a wiper bearing against the periphery of the applying-roll between the body of cement and the said applying portion, and means for adjusting said wiper relatively to the periphery of the applying-roll.

4. A cementing-machine comprising a cement-applying roll having pockets in its periphery, a bed-roll which supports the work under the applying-roll and is pressed yieldingly toward the applying-roll, a cement-preparator having end portions bearing against the ends of the applying-roll and a wiper bearing against the periphery of the applying-roll between the body of cement and the said applying portion, said preparator being pivoted above the said wiper, so that the latter is adapted to swing edgewise toward the applying-roll, and means for exerting pressure on said preparator in the direction required to press the said wiper against the periphery of the applying-roll.

5. A cementing-machine comprising a cement-applying roll having pockets in its periphery, a bed-roll which supports the work under the applying-roll and is pressed yieldingly toward the latter, a cement-preparator adapted to hold a body of cement against one side of the applying-roll above its cement-applying portion, and having a wiper which bears against the periphery of the applying-roll between the body of cement and the said applying portion, and a reservoir adapted to supply cement to the preparator, said reservoir having an outlet extending into said body of cement, and being practically air-tight above said outlet, whereby the flow of cement to the preparator is automatically checked by the rise of cement in the latter.

698,963. FURNITURE-CASTER. JOHN W. KEMMER, Cecil, Ga. Filed Nov. 14, 1901. Serial No. 82,708. (No model.)

Claim.—1. A caster comprising an X-shaped spring-frame the arms of which are free to vibrate and provided with center-wheels at their free ends, substantially as specified.

2. In a caster, the combination of a pair of resilient metallic strips curved to form an X-shaped frame, a cross connecting the strips at the point of crossing, and center-wheels mounted upon the ends of the strips which form the radial arms of the frame, substantially in the manner set forth.

3. A caster comprising, in combination, an X-shaped frame formed of a pair of curved spring-metal strips having an interlocking engagement at the point of crossing, the free ends of the strips forming independently-yieldable radial arms, a center-wheel mounted on each arm, a stem passing through the crossed portion of the strips, and means for clamping the stem and strips together, substantially as set forth.

698,964. DENTAL ARTICULATOR. MATTHEW H. KINN, Detroit, Mich. Assignor to the Kinn Dental Manufacturing Company. Filed Nov. 18, 1901. Serial No. 69,661. (Model.)

Claim.—1. In an articulator the combination of the jaw members, a hinge uniting the jaw members, means forming a part of the hinge structure for allowing a direct lateral movement of one or both of the jaw members independently of the hinge movement whereby a jaw member may be moved laterally coincident with the articulatory movement thereof.

2. In an articulator, the combination of the jaw members hinged together to articulate and means for allowing a direct lateral movement of either of said members in a plane parallel with its companion member.

3. In an articulator, the combination of the jaw members, a hinge uniting said jaw members, a slotted plate rotatably seated in the members of one of the jaws the plates of the hinge uniting said jaws passing through the slots in said plates and means for adjusting said plates to change the angle of said slots.

4. In an articulator, the combination of the jaw members, a hinge uniting said jaw members, said hinge affording a lateral movement of the jaw member as well as an articulation thereof, slotted plates rotatably seated in the members of one of the jaws, the plates of the hinge passing through the slots of said slotted plates and entering the opposite jaw members, said plates lying in said slots, means for adjusting said slotted plates and for locking them when adjusted.

5. In an articulator, the combination of the jaw members hinged together, said jaw members having detachable bows adapted to carry the teeth, the upper bow having a thread upon one end thereof and an adjustable nut screwed onto said threaded portion adapted to engage the jaw member for the purpose of adjusting the bow and maintaining said adjustment when the bow is removed.

6. In an articulator, the combination of the jaw members hinged together, an inclined plane supported from the lower jaw member, an adjusting-screw carried by the upper jaw member adapted to engage the surface of said inclined plane.

7. In an articulator the combination of the jaw members, a hinge uniting the jaw members, means for allowing a direct lateral movement of a jaw member in a plane parallel with its companion member independently of the hinge movement whereby a combined lateral and articulatory movement is obtained, and means for automatically returning the movable parts to their normal position.

8. In an articulator the combination of the movable members adapted to carry the teeth, a hinge uniting said members constructed to afford a lateral and an articulatory movement, means for adjusting said hinge to allow the teeth to articulate and occlude in the lateral movement to accommodate any curve of the jaw.

9. In an articulator the combination of the movable members adapted to carry the teeth, a hinge uniting said members, said hinge being constructed to allow a lateral and a longitudinal reciprocation of a hinge member as well as an articulatory movement thereof, and means for automatically restoring the parts to their normal position after a longitudinal or lateral movement.

10. In an articulator the combination of the jaw members united by a hinge having a normal axis of oscillation, means for allowing a movement of the plates of the hinge away from said normal axis in a plane diametrical thereto, and means for changing the plane of travel of said plates in a direction concentric with said normal axis.

11. In an articulator the combination of the jaw members, a hinge uniting said members, said hinge affording a lateral and an articulatory movement of a jaw member, the plates of the hinge having sockets in their ends and the springs fixed to one of the members of the jaw and entering freely the sockets of said plates.

698,965. CONNECTION OF STRIKERS TO MOTOR-VEHICLES FOR MECHANICALLY OPERATING ELECTRIC SWITCHES. WILLIAM KUNHAM, London, England. Filed Aug. 28, 1901. Serial No. 12,042. (No model.)

Claim.—1. In a device for operating electric switches, the combination with a practically horizontal member having a downwardly-extending striking-arm at one end thereof to rest upon the tappet mechanism, of a vertical pivot-pin upon which the other end of the horizontal member is freely mounted, and means for connecting the said pivot-pin to the axle-box of the car-wheel axle, substantially as set forth.

2. In a device for operating electric switches, the combination with a downwardly-extending striker to rest upon the tappet mechanism, of a practically horizontal arm upon one end of which the striker is carried, and a vertical pivot-pin supported from the axle-box of the car-wheel axle, upon which pivot-pin the other end of the horizontal arm is mounted so that the said arm is free to turn in a horizontal plane, and whereby the striker can freely follow the curves of the track-rail, substantially as set forth.

3. In a device for operating electric switches, the combination with a downwardly-extending striker to rest upon the tappet mechanism, of a practically horizontal arm upon one end of which the striker is carried, a vertical pivot-pin supported from the axle-box of the car-wheel axle, upon which vertical pivot-pin the other end of the horizontal arm is mounted, so that the said arm is free to turn in a horizontal plane, and means by the striker can freely follow the curves of the track-rail, and means

for elastically maintaining the acting end of the striker in a working position in the direction of its action substantially as set forth.

4. In a device for operating electric switches, the combination with a downwardly-extending striker, to rest upon the tappet mechanism, of a practically horizontal arm upon one end of which the striker is carried, a frame connected to the motor-vehicle, vertical guides in the frame and sliding axle-boxes in the guides to carry the wheel-axle, so that the frame may move vertically upon the axle-boxes, a vertical pivot-pin supported from the axle-box of the car-wheel axle, upon which pivot-pin the striker-carrying arm is mounted so that the said arm is free to turn in a horizontal plane, and means for elastically maintaining the acting end of the striker in a working position in the direction of its action substantially as set forth.

698,966. MACHINE FOR PRODUCING MATRICES FOR STYLOTYPE-PLATES. EDWIN LIND, Philadelphia, Pa. Filed Nov. 20, 1901. Serial No. 809,440. (No model.)

Claim.—1. In a machine of the class described, a writing-machine, a printing-machine provided with a plurality of fonts of type of different faces, and electromagnetic devices for actuating the type-arms of said printing-machine, said electromagnetic devices being in circuit with suitable connections controlled by the keyboard of the writing-machine.

2. In a machine of the class described, a writing-machine, a printing-machine provided with a plurality of fonts of type of different faces, electromagnetic devices for actuating the type-arms of said printing-machine, a separate circuit for the electromagnetic devices of each type-font, and means for controlling each of said circuits.

3. A printing-machine provided with a plurality of fonts of type of different faces, each font being operated by an independent system of electromagnetic devices controlled by a type-writer circuit, and a switch for throwing into operation any font desired, in combination with a type-writer located in said circuit for operating any one of said fonts.

4. A printing-machine provided with a plurality of fonts of type of different faces, each font being operated by an independent system of electromagnetic devices controlled by a type-writer circuit, a switch for throwing into operation any font desired, and electromagnetic devices for controlling the movements of the carriage of the machine, in combination with a type-writer located in said circuit for operating any one of said fonts.

698,967. CASE-REGISTER. WILLIAM KUNHAM and FRANK FLEMM, Munich, Germany, assignors to the Maschinenfabrik Hermann Döring & Co., Munich, Germany. Filed June 2, 1900. Serial No. 12,060. (No model.)

Claim.—1. In a cash-register apparatus, the combination of a registering mechanism, an indicating mechanism, a cash-drawer, an operating-lever, means controlled thereby for releasing the registering device, means for keeping the drawer locked until the amount of cash is indicated by the indicator, and means for releasing said drawer-locking means carried by said actuating-lever, substantially as described.

2. In a cash-register apparatus, the combination of a registering mechanism, an indicator, and a cash-drawer, an actuating-lever, means

controlled thereby for operating the registering mechanism, means for locking the drawer, means for preventing the release thereof when indicating the amount of cash by the indicator, and means for releasing the cash-drawer on a subsequent further depression of the actuating-lever, substantially as described.

3. In a cash-register apparatus, the combination with an indicating mechanism of an operating-lever, means controlled thereby for operating the indicating mechanism, means for locking the operating-lever against a full downward stroke at one operation, and means for releasing said lever for moving the remainder of the stroke after the indicating mechanism has been reset by the first portion of the stroke of said lever, substantially as described.

4. In a cash-register apparatus, the combination with an operating-lever of a piston for registering the movement of said lever, having a heart-shaped groove, and a fixed pin on the frame of the register for engaging the latter so as to limit the movement of the piston, substantially as described.

5. In a cash-register apparatus, the combination with a cash-drawer and an operating-lever, of a piston having an approximately heart-shaped groove and a fixed pin on the frame of the register engaging the said groove, a hook for locking the cash-drawer, a pin-and-dot connection between the operating-lever and the said hook for permitting a partial movement of the lever without releasing the hook, substantially as described.

6. In a cash-register apparatus the combination with indicating device and an operating-lever, of catches for locking the indicating device, means for disengaging the catches, a shaft having an arm provided with an articulated part and a finger on the operating-lever cooperating with the articulated part, whereby said arm will be actuated when the lever is moved in one direction, but not when reversed, substantially as described.

7. In a cash-register apparatus the combination with indicating device and an operating-lever, of a piston having a heart-shaped groove, and a fixed pin engaging the latter, catches for locking indicating device, means for disengaging the catches comprising a shaft having an arm provided with an articulated part, and a finger on the operating-lever cooperating with the articulated part, substantially as described.

8. In a cash-register apparatus the combination with indicating device, a cash-drawer and an operating-lever, of a piston having a heart-shaped groove, and a pin engaging the latter, a hook for locking the drawer, a pin-and-dot connection between the operating-lever and the hook for locking the drawer, catches for locking the indicating device, means for disengaging the catches and actuated upon by the operating-lever, a shaft having an arm provided with an articulated part, and a finger on the operating-lever cooperating with the articulated part, substantially as described.

9. In a cash-register apparatus, the combination of an indicating mechanism, a registering mechanism, an operating-lever, a spring-actuated bell-crank lever normally retaining the registering mechanism and the indicating mechanism in an uncoupled condition, and a spring-con-

trolled catch projecting laterally from the operating-lever and designed to strike one arm of the bell-crank lever for moving said bell-crank lever for effecting the coupling of the said mechanisms, substantially as described.

10. In a cash-register apparatus, the combination with an indicating device, an actuating-lever, and a cash-drawer having a catch in one edge thereof, of means engaging said catch for locking the drawer, a second locking means, means for releasing both locks, and means controlled by said actuating-lever for setting the indicating device before the release of said locks, substantially as described.

11. In a cash-register apparatus, the combination with a slightly-mounted registering mechanism, an indicating mechanism, and an operating-lever, of an articulated catch carried thereby, means coupling said registering and indicating mechanisms, and means for shifting the registering mechanism for uncoupling said parts, comprising a bell-crank lever adapted to be actuated by said articulated catch, and a bar pivotally connecting said bell-crank lever with the registering mechanism, substantially as described.

12. In a cash-register apparatus, the combination with an actuating-lever, and an indicating mechanism, of slides provided with teeth on their upper edges for operating said indicating mechanism, locking-teeth on the under edges of said slides, hooks engaging the said locking-teeth, a shaft mounted and laterally shiftable in the angle of the hooks, a lever carried by said shaft, by which it may be caused to disengage said hooks from said locking-teeth, and means on the actuating-lever for engaging the said shaft-lever, substantially as described.

698,968. FILE FOR MILES. FRANK E. KRAE, Chicago, Ill., assignor to R. L. Krag, Chicago, Ill. Filed Jan. 22, 1900. Serial No. 1,201. (No model.)

Claim.—1. In a temporary binder, in combination, a plate 10 having post-receiving apertures, a plurality of posts 12 fixed in said plate and having lateral notches adjacent to their ends; a plate 11 having apertures for receiving the posts 12, a plurality of posts 13 fixed in the plate 11 and entering the apertures of the plate 10; a plate 14 in sliding engagement with the plate 11, and having apertures to receive the posts 12, and a spring for controlling this plate so as to draw its solid portions into engagement with the notches of said posts, substantially as described and for the purpose specified.

2. In a file for bills and the like, in combination, a pair of plates; a plurality of posts fixed in each plate and adapted to engage apertures in the other plate; a jointed cover for inclosing the above-named members and to which one of said plates is secured; and a clamp for detachably engaging the cover with the plate not so secured.

698,969. LOCK FOR LOOSE-LEAF BINDERS. FRANK E. KRAE, Chicago, Ill., assignor to R. L. Krag, New York, N. Y. Filed July 2, 1900. Serial No. 63,200. (No model.)

Claim.—1. In a loose-leaf binder, in combination, a pair of binding-plates one of which is provided with an aperture having a way offset therefrom, leaf-retainers fixed to the binding-plates, an oscillating toothed rod carried by the apertured binding-plate and having its end projecting into the said aperture, a finger extending from the rod and playing in the said way, a housing-plate secured to the other binding-plate and which receives the toothed rod, a spring-pressed pawl pivoted within the housing-plate and engaging the toothed rod, and a projection at the end of the rod and which is moved into the path of the pawl when the rod is oscillated.

2. In a loose-leaf binder, in combination, a pair of binding-plates one of which is provided with an aperture having a curved way offset therefrom, telescoping leaf-retainers fixed to the binding-plates, a plate secured to the apertured binding-plate and having an opening extending with the said aperture, an oscillating toothed rod journaled in the opening of the plate and having its end projecting into the aperture of the binding-plate, a nut secured on the end of the rod, a finger on the nut

playing in the said curved way, a pin in the path of the finger, a curved housing-plate secured to the other binding-plate for receiving the toothed rod, and a spring-pressed pawl pivoted within the housing-plate and engaging the tooth of the rod.

698,970. GAR-COUTLING. HARRY T. KRAMER, Cleveland, Ohio, assignor to the National Malleable Castings Company, Cleveland, Ohio, a Corporation of Ohio. Filed Aug. 21, 1891. Serial No. 72,126. (No model.)

Claim.—1. A coupler having a coupler-head and knuckle, the front walls of the head and knuckle being substantially parallel when the knuckle is closed, and the coupler-head being connected with the ear by a pivotal connection substantially coincident with the center of motion of the ear-truck.

2. A coupler having a coupler-head and knuckle, the front walls of the head and knuckle being substantially parallel when the knuckle is closed; and the coupler being pivotally connected with the ear at a point back of the position of the end sill.

3. A coupler having a coupler-head and knuckle, the front walls of the head and knuckle being substantially parallel when the knuckle is closed, and substantially at right angles to the line of draft of the coupler, and the coupler being connected pivotally with the ear.

4. The combination of couplers having coupler-heads and pivoted knuckles shaped to interlock substantially inflexibly together, said couplers being connected pivotally to their respective ears at points substantially coincident with the center of motion of the ear-trucks.

5. The combination of couplers having coupler-heads and pivoted knuckles shaped to interlock substantially inflexibly together, said couplers being connected pivotally to their respective ears at points back of the position of the end sill.

698,971. DROP-BUTTON FOR AIR-PUMP. JOHN A. KRAMER, Bismarck, N. D. Filed Jan. 12, 1892. Serial No. 96,268. (No model.)

Claim.—1. In an air-box of a locomotive, the combination of drop-downs forming the bottom thereof, one of said doors carrying a platform integral therewith and underlapping the other door, an operating-shaft, chains connected to said operating-shaft and said doors, means to operate said door and the operating-shaft, and means independent of the said chains for preventing the accidental releasing of the said door, substantially as described.

2. In an air-box for locomotives and the like, the combination of drop-downs hinged to the sides of said box forming the bottom thereof, a plate carried by one of said doors underlapping the other door, an operating-shaft carrying a crank-handle, chains connecting said shaft and doors, and inwardly-inclined plates secured to the inner sides of said box near the bottom and above the hinges thereof, said plates being inclined at an angle, substantially as described.

3. In an air-box for locomotives and the like, the combination of drop-downs hinged to the sides of said box forming the bottom thereof, a plate carried by one of said doors underlapping the other door, an operating-shaft carrying a crank-handle, arms secured on the operating-shaft to which the chains are attached, plates secured to the inner sides of said box near the bottom thereof, said plates being inclined at an angle, aatchet-wheel carried by said operating-shaft, and a locking-pawl, a bar extending from the doors, a rod pivoted to a platform, said rod supporting said bar and means for releasing the same, all parts being arranged and operating substantially as shown and described.

698,972. APPARATUS FOR TELEPHONE TALK-LINE. THOMAS A. LANE, Chicago, Ill., assignor to East Continental Telephone Company, Chicago, Ill., a Corporation of Illinois. Filed June 12, 1892. Serial No. 68,913. (No model.)

Claim.—1. In a system of communication, the combination with a signal-circuit, of means operated by a talk-piece controlling said circuit, a local circuit, means in said local circuit controlling the transfer of the talk-piece from its operative engagement with said means, and means for making and breaking said local circuit, substantially as described.

2. In a telephone system, the combination with a telephone instrument, of means operated by a talk-piece for controlling a signal at a central station, a local circuit, means in said local circuit controlling the transfer of the talk-piece from its operative engagement with said means, and means for making and breaking said local circuit, substantially as described.

3. In an apparatus of the character described, the combination with a plurality of chutes, of means for controlling the passage of an article into a predetermined one of said chutes, an arm rigidly secured to said means, a pivoted armature normally in alignment with said arm, a rail-rod connection between said armature and said arm, and a plurality of magnets for actuating said armature, and an independent circuit for energizing each of said magnets.

4. In an apparatus of the character described, the combination with a plurality of chutes, of a main chute communicating therewith, a switch for connecting one of said communicating chutes with the main chute, an arm rigidly secured to said switch, an armature for operating said switch, a spring-rod interposed between said armature and said arm, and magnets secured on opposite sides of said armature, and an independent circuit for each of said magnets.

5. In a telephone instrument, the combination with a plurality of chutes, of means for controlling the passage of a talk-piece into a predetermined one of said chutes, a plurality of magnets for actuating said means, a local circuit at the instrument for energizing one of said magnets, a circuit for energizing the other of said magnets, and means for controlling each of said circuits, substantially as described.

6. In a telephone instrument, the combination with a plurality of chutes, of means for controlling the passage of a talk-piece into a predetermined one of said chutes, a plurality of magnets for actuating said means, a local circuit at the instrument for energizing one of said magnets, a controller for said circuit operated by the telephone-receiver support, an independent circuit for energizing the other of said magnets, and means for controlling said independent circuit, substantially as described.

7. In a telephone instrument, the combination with a plurality of chutes, of means for controlling the passage of a talk-piece into a predetermined one of said chutes, a plurality of magnets for actuating said means, a local circuit at the instrument for energizing one of said magnets, a controller for said circuit operated by the telephone-receiver support, a second controller for said circuit operated by the talk-piece, an independent circuit for energizing the other of said magnets, and means for controlling said independent circuit, substantially as described.

8. In a telephone instrument, the combination with a plurality of chutes, of means for controlling the passage of a talk-piece into a predetermined one of said chutes, a plurality of magnets for actuating said means, a local circuit at the instrument for energizing one of said magnets, contacts in said circuit adapted to be closed by the telephone-receiver when engaging its support, other contacts in said circuit adapted to be closed by the talk-piece, and means for energizing the other of said magnets, substantially as described.

9. In combination with an apparatus of the character described having an opening adapted to receive a talk-piece, of electrically-actuated means for transferring the talk-piece to a freely-accessible position, and means local to the apparatus for energizing the said electrically-actuated means.

10. In combination with an apparatus having an opening adapted to receive a talk-piece, of electrically-actuated means for transferring the talk-piece to a freely-accessible position, means located at the apparatus for controlling the said electrically-actuated means, and other means for transferring the talk-piece to a position inaccessible to the public, substantially as described.

11. In combination with a telephone instrument adapted to receive a talk-piece, of electrically-actuated means for transferring the talk-piece to a freely-accessible position, a circuit actuating said electrical means, and contacts for closing said circuit operated by the telephone-receiver support, substantially as described.

12. In combination with a telephone instrument adapted to receive a talk-piece, of electrically-actuated means for transferring the talk-piece to a freely-accessible position, a circuit including said electrical means, means normally closed by the telephone-receiver engaging its support, and a controller in said circuit adapted to be operated by the talk-piece to completely close said circuit and thereby actuate said electrical means, substantially as described.

13. In combination with a telephone instrument adapted to receive a talk-piece, of electrically-actuated means for transferring the talk-piece to a freely-accessible position, a circuit including said electrical means, a circuit-controller operated by the talk-piece to close said circuit and thereby actuate the electrical means, and means for making and breaking said circuit, substantially as described.

14. In combination with a telephone instrument adapted to receive a talk-piece, of electrically-actuated means for transferring the talk-piece to a freely-accessible position, a circuit including said electrical means, a plurality of circuit-controllers located at said instrument for closing said circuit through both of which the current passes to actuate said electrical means, substantially as described.

15. In a telephone system, the combination with a telephone instrument adapted to receive a talk-piece, of a switch controlling the transfer of the talk-piece to a freely-accessible position or to a position inaccessible to the public, a plurality of magnets for actuating said switch, an independent circuit for energizing each of said magnets, means whereby the user of the telephone may control the circuit energizing the magnets for transferring the talk-piece to a freely-accessible position, and means whereby the operator at central may control the circuit for energizing the magnets to transfer the talk-piece to a position inaccessible to the public, substantially as described.

698,973. ANIMAL-TRAP. HERMAN LARSEN, WILMINGTON, Conn. Filed Dec. 22, 1891. Serial No. 87,578. (No model.)

Claim.—1. A trap of the character described, comprising a base normally upwardly spring-pressed arms, a trigger for holding said arms apart, and said arms having rounded trigger-curves, substantially as described.

2. A trap of the character described, comprising a base, normally upwardly spring-pressed arms, an outwardly-extending stud carried by the opposite side of each arm and a trigger resting between said studs, substantially as described.

3. A trap of the character described, comprising a base, normally upwardly spring-pressed arms, an outwardly-extending stud carried by the opposite side of each arm, and a trigger between said arms and having tapered ends engaging said studs, substantially as described.

4. A trap of the character described, comprising a base, normally upwardly spring-pressed arms, an outwardly-extending horizontal rounded stud carried by the opposite side of each arm, and a trigger resting between said studs, substantially as described.

5. A trap of the character described, comprising a base, arms pivoted thereto and normally upwardly spring-pressed, an outwardly-extending horizontal rounded stud carried by the opposite side of each arm, and a trigger having tapered ends resting on and supported between said studs, substantially as described.

6. A trap of the character described, comprising a base, a stud carried thereby and having a vertical slot therein, arms or jaws pivoted side by side in the lower end of said slot, a spring surrounding the stud, and normally forcing the arms upward, a pin transverse said slot between the arms, an outwardly-extending horizontal rounded stud carried by the opposite side of each arm, and a trigger having tapered ends resting on and supported between said studs, substantially as described.

7. A trap of the character described, comprising a base, a stud carried thereby and having a vertical slot therein, arms or jaws pivoted side by side in the lower end of said slot, a spring surrounding the stud and

normally forcing the arms upward, a pin transverse the slot between the arms, an outwardly-extending horizontal rounded stud carried by opposite sides of said arms, and a trigger having tapered ends resting on and supported between said studs, substantially as described.

8. A trap of the character described, comprising a base, a stud carried thereby and having a vertical slot therein, jaws within said slot side by side, a pin passing transversely through said stud and arms, a V-shaped spring having its ends surrounding said stud, and one end normally forcing the arms upward, a pin transverse the slot between the arms, an outwardly-extending horizontal rounded stud carried by the opposite side of each arm, and a trigger having tapered ends resting on and supported between said arms, substantially as described.

9. A trap of the character described, comprising a base, arms pivoted thereto and normally upwardly spring-pressed, a trigger between said arms, and said arms having horizontally-projecting trigger-curves, substantially as described.

698,974. BUT-LOCK. LOUIS LEBLANC and SAMUEL FURST, HILLSBORO, Pa. Filed Dec. 12, 1891. Serial No. 68,368. (No model.)

Claim.—1. The combination with a bolt having a square end, and a nut having oppositely-arranged rods passed therethrough and rigidly secured to said nut with the free ends of the rods extending beyond said square end of the bolt, and a locking device comprising in its entirety an entirely-removable plate adapted to receive said square end of the bolt and to have the said free ends of the rods pass therethrough, said plate being engaged on said rods and moved horizontally to engage said square end of the bolt, substantially as described.

2. The combination with a bolt having a square end, and a nut, of rods passing through openings in the nut and having their free ends extending beyond the square end of the bolt, and a locking device comprising in its entirety a removable plate having a square central aperture to receive said square end of the bolt, and a series of smaller apertures located between the said central aperture and the edges of the plate, said smaller apertures adapted to receive the free ends of the said rods, whereby the plate can be slid thereon and have its central aperture brought into engagement with the bolt's square end.

698,975. ASHTYLENE-GAS GENERATOR. THOMAS H. LEWIS, London, England. Filed June 4, 1892. Serial No. 15,988. (No model.)

Claim.—1. In a cartridge for use in an acetylene or similar lamp, the combination with an inclosing case, of a corrugated or plaited strip of absorbent material arranged on the bottom thereof in such manner as to serve as a yielding confining and dividing frame to support the charge upon the upper side and yield as said charge increases in bulk with decomposition, and means located on the under side of the strip for extracting said strip with hydrating fluid.

2. In a cartridge for use in an acetylene or similar lamp, the combination with an inclosing case of a corrugated or plaited strip of absorbent material arranged therein in such manner as to serve as a yielding confining and dividing frame to support the charge on one side, a central non-conducting rod to keep the lower ends of the corrugations or plaites from contact, and means whereby said rod may be exposed to the current of a hydrating fluid, to absorb and conduct moisture therefrom to the contacting surfaces of the charge resting on its plate.

3. In a cartridge for use in an acetylene or similar lamp the combination with a non-conducting casing having a recess formed in its bottom wall, and an opening through the floor of said recess, of an absorbent pad set within said recess.

4. In a cartridge for use in an acetylene or similar lamp, the combination with a non-conducting casing having a recess formed in its bottom wall, an opening through the floor of said recess, and a ledge or shoulder near the top of the casing, of an absorbent pad set within said recess, a tilted metal plate fitting snugly into said shoulder and a corrugated or plaited strip of absorbent material dividing said casing to support the charge upon its upper side and having its ends passed through the slit in said plate.

5. In a cartridge for use in an acetylene or similar lamp, the combination with a non-conducting case having a recess formed in its bottom wall, an opening *f* through the floor of said recess, and a ledge or shoulder *f'* near the top of the recess, of an absorbent pad set within said recess, a cork ring overlapping the edge of said pad and the ledge, a perforated metal plate covering said ring, and a plated or corrugated strip of absorbent material dividing said casing to support the charge therein and having its ends passed through said perforated plate and in contact with the absorbent pad.

698,976. SLAVE FOR PROTECTING INSULATOR-PIN. FRANK H. LORR, Victor, N. Y. Filed Nov. 11, 1901. Serial No. 51,914. (No model.)

Claim.—1. A slave for an insulator-pin, constructed of porcelain or similar material, having a flange at the bottom extending out to a point beyond the point at which the base of the insulator would intersect the cross-arm in case the insulator-base was extended.

2. An insulator-slave constructed of porcelain or similar material having a flange at its lower end and adapted to rest upon the cross-arm and extending beyond a point upon the cross-arm which would be in vertical alignment with the base of the insulator.

3. A slave for an insulator constructed of porcelain or similar material, having a flange at the bottom adapted to rest upon the cross-arm and having the sides which rest upon the upper face of the cross-arm extended beyond the point upon the cross-arm in vertical alignment with the base of the insulator and having the sides of said flange depressed for the purpose of forming a head to protect the edges of the cross-arm from the elements.

4. A slave for an insulator constructed of porcelain or similar material, having a flange at the bottom adapted to rest upon the cross-arm and having the sides which rest upon the upper face of the cross-arm extended beyond the point upon the cross-arm in vertical alignment with the base of the insulator and having the sides of said flange depressed for the purpose of forming a head to protect the edges of the cross-arm from the elements.

5. A slave for an insulator constructed of porcelain or similar material, having a flange at the bottom adapted to rest upon the cross-arm and having the sides which rest upon the upper face of the cross-arm extended beyond the point upon the cross-arm in vertical alignment with the base of the insulator and having the sides of said flange depressed for the purpose of forming a head to protect the edges of the cross-arm from the elements, the lower edge of said depressed portion being semicircular for the purpose specified.

6. A slave for an insulator-pin constructed of porcelain or other insulating material surrounding the pin at the point where said pin meets the cross-arm and out of contact with the insulator and bolt which secures the pin to the cross-arm.

7. A slave for an insulator-pin constructed of porcelain or other insulating material surrounding the pin at the point where said pin meets the cross-arm, said slave being enlarged at its lower end and out of contact with the insulator and bolt which secures the pin to the cross-arm.

8. A slave for an insulator-pin constructed of porcelain or other insulating material surrounding the pin at the point where said pin meets the cross-arm, said slave increasing in size as it approaches its lower end and out of contact with the insulator and bolt which secures the pin to the cross-arm.

698,977. BRICKLAYS DOLLAR-FURNACE. JOHN G. LORR and JOHN LORR, St. Louis, Mo. Filed Dec. 4, 1901. Serial No. 54,998. (No model.)

Claim.—In a brick-furnace, the bridge-wall 1 built with a plurality of air-passages 2 leading from the sub-pit backwardly below the grate, then upwardly to a point some distance above the grate and then forwardly to the fire-box, then leaving the solid wall 5 back of and above the grate to support the fuel and to discharge the air which passes through the bridge-wall above the fuel and not through the fuel, the lower ends of the air-passages 2 being formed rectangular in lying the brick and

the pillars 6 between said air-passages serving to support the solid wall 5; the casing 4 placed upon the solid wall 5 and supporting the upper portion of the bridge-wall, said casing having longitudinally-extending slots forming air-passages 3 and said upper portion of the bridge-wall projecting forwardly a slight distance over the casing and over the fuel so as to force the air coming through the bridge-wall to pass forwardly over the fuel; substantially as specified.

698,978. TROLLEY-WHEEL. GEORGE LORR, Norwalk, Ohio, assignor to William R. Mowery and Stephen Shortt, Baltimore, Ohio. Filed Sept. 7, 1901. Serial No. 74,048. (No model.)

Claim.—1. A trolley-wheel having a body portion provided with a central base and a peripheral groove, a bushing secured in said base having reduced ends providing shoulders, flanges having central openings mounted on said bushing over the shoulders, and sets adapted to fit the ends of said bushing and bear against the shoulders and sides of the flanges, as set forth.

2. A trolley-wheel having a body portion provided with a central base and a peripheral groove, seats or depressions in the sides thereof surrounding said base, a bushing secured in said base having reduced ends providing shoulders, removable flanges mounted on said bushing and having projections on their inner sides adapted to be seated in the seats or depressions in the body portion, and means adapted to fit the ends of said bushing and bear against the shoulders and sides of the flanges, as set forth.

3. A trolley-wheel having a body portion provided with a central base and a peripheral groove, and provided on each side thereof with a projection, a bushing secured in said base having reduced ends providing shoulders, flanges having central openings and provided on their inner sides with circular grooves adapted to receive the projections on the sides of the body portion, and means adapted to fit the ends of said bushing and bear against the shoulders and sides of the flanges, as set forth.

4. A trolley-wheel having a body portion provided with a central base and a peripheral groove, circular seats or depressions in the sides thereof surrounding said base, a bushing secured in said base having reduced ends providing shoulders, removable flanges having circular projections and grooves on their inner sides, circular seats or depressions on their outer sides, and means adapted to fit on the ends of said bushing and bear against the shoulders and sides of said flanges, as set forth.

698,979. TROLLEY-ARM HEAD. FRANK J. LORR, Inventor, N. Y. Filed Aug. 31, 1901. Serial No. 74,049. (No model.)

Claim.—1. A trolley-arm head comprising yoke and guard-flanges, which later on their upper sides are concentric with the wheel-flange and have continuations extending rearwardly and downwardly to a point below the bottom of the groove of the wheel, said continuations being longitudinally disposed from a point in vertical line with the axis of the wheel rearward when said wheel and head are in operative position, as set forth.

2. A trolley-arm head comprising a yoke and guard-flanges there-

on, said flanges on their upper sides being concentric with the wheel-flange and having continuations extending rearwardly and downwardly to a point below the bottom of the groove of the wheel, said continuations being longitudinally disposed from a point in vertical line with the axis of the wheel when said wheel and head are in operative position, said flanges being provided upon their inner faces in vertical line with the axis of the wheel with tubular protuberances, as set forth for the purpose specified.

698,980. APPARATUS FOR THE MANUFACTURE OF GLASS. ST. JULIAN LORR, Aachen, Germany. Filed Dec. 20, 1900. Serial No. 74,100. (No model.)

Claim.—1. In a glass-furnace, provided with an annular space to contain the liquid mass, the combination therewith of an inverted-bell-shaped stirrer and mixer having its edge in said annular space, and means for vertically reciprocating the bell and rotating it on its vertical axis, substantially as described.

2. In a furnace of the character described, the annular space *C*, having inner walls 7 surrounding a space *E*, in combination with the inverted-bell-shaped stirrer *D* having its lower edge in said space *C* and below the top of the walls 7, whereby the mass admitted to space *C* is compelled to pass under the edge of the bell *D* in order to escape over walls 7, substantially as described.

3. In a furnace of the character described provided with annular space *C* having inner walls 7 including space *E*, the combination of the bell-shaped stirrer *D* inverted with its edge in space *C* below the top of the wall 7, and a central pipe 9 in communication with a gas-supply and discharging under the bell-shaped stirrer, substantially as described.

4. In a furnace of the character described, a stirrer or mixer consisting of a rotatable rod or support, a perforated metal plate secured to its lower end, and an inverted bell of clay formed on said plate, the clay on the opposite sides of the plate being held together through the openings in the plate, substantially as described.

698,981. BRICKLAYS FURNACE FOR MAKING GLASS. ST. JULIAN LORR, Aachen, Germany. Filed Dec. 20, 1900. Serial No. 74,101. (No model.)

Claim.—1. In an electric smelting-furnace, the combination of a smelting-chamber having a longitudinal discharge-opening and a single negative electrode longitudinally arranged in said discharge-opening with a plurality of transversely-arranged positive electrodes in the same horizontal plane on each side of the negative, substantially as described.

2. In an electric smelting-furnace, the combination with a hopper-shaped smelting-chamber having a longitudinal bottom opening, and provided with vertically-extended corrugations in the lower surface of its side walls, of a single horizontal electrode lying longitudinally in the said

opening, and a plurality of transverse electrodes in the same horizontal plane ending near the longitudinal electrode and located in the vertical planes of the grooves of the corrugated sides, substantially as described.

3. In an electric smelting-furnace, the combination of a smelting-chamber having a longitudinal discharge-opening and a single negative electrode arranged longitudinally in said discharge-opening, with a plurality of transversely-arranged positive electrodes in the same horizontal plane on each side of the negative electrode, the negative electrode being prism-shaped in cross-section and presenting opposite sharp corners toward the positive electrodes, substantially as described.

4. In an electric smelting-furnace, the combination of a smelting-chamber having a longitudinal discharge-opening and a single negative electrode longitudinally arranged in said discharge-opening, with a plurality of transversely-arranged positive electrodes in the same horizontal plane on each side of the negative electrode, the negative electrode being bored longitudinally and transversely for the passage of air and gas, substantially as described.

5. In an electric smelting-furnace, the combination of a smelting-chamber having a longitudinal discharge-opening and a single negative electrode longitudinally arranged in said discharge-opening, with a plurality of transversely-arranged positive electrodes in the same horizontal plane on each side of the negative electrode, the negative electrode being bored longitudinally, having one end of the said bore closed, and there being provided side outlets from the bore, whereby gas and air may be passed through, substantially as described.

698,982. SWITCH-THROWING DEVICE. FANN LUTHER, Allegheny, Pa. Filed Nov. 8, 1901. Serial No. 51,945. (No model.)

Claim.—1. In combination with a pivoted switch-tongue, a throwing-rod pivoted thereto, a pivoted lever to which the outer end of said throwing-rod is connected, a like lever pivoted to the first-mentioned lever whereby when the latter is actuated the switch-tongue is moved away from the main track, a throwing-rod pivoted to the first-mentioned throwing-rod, and a lever to which the outer end of said second-named throwing-rod is attached for returning the switch-tongue to its normal position, substantially as described.

2. In a switch, the combination with the main rail and the side rail, of a switch-tongue pivoted to a saddle-plate, a throwing-rod pivoted to said switch-tongue, a pivoted lever to which the outer end of said throwing-rod is connected, a throwing-rod connected to the first-mentioned throwing-rod, and a pivoted lever to which the said second-named throwing-rod is connected, substantially as described.

698,983. TANK-HEATER. MATTHEW LYDER, Maitland, Mo.
Filed Sept. 4, 1901. Serial No. 74,890. (No model.)

Claim.—1. A tank-heater comprising a water-jacket forming the top, sides and one end wall of a combustion-chamber, a front wall completing the same, a door formed therein, a grate within said chamber, and a flue of approximately the width of the combustion-chamber leading from the bottom of said chamber for conducting the products of combustion therefrom, substantially as described.

2. In a tank-heater, the combination with a tank, of a water-jacket beneath the same, means for permitting communication between the interior of said jacket and said tank, the said jacket forming the rear, top and side walls of a combustion-chamber, a front wall and base completing the same, a grate within said chamber, a door formed in the said front wall for the introduction of fuel to said grate, means carried by said door for regulating the supply of atmosphere to the combustion-chamber, and a flue of approximately the width of the combustion-chamber penetrating said base, near the rear end thereof and adapted to conduct the products of combustion therefrom, the structure being such that air admitted through said regulator is directed downwardly through said grate and out through said flue, substantially as described.

698,984. COIN-CONTROLLED VENDING-MACHINE. FRED LYDER, Johnston, N. Y. Filed June 1, 1901. Serial No. 66,714. (No model.)

Claim.—1. In a vending-machine, a plurality of receptacles for goods to be sold, a discharging device for each receptacle, a coin-receiver for each discharging device, electrically-operated means controlled by a coin for releasing the discharging device, chute leading to said receiver, a coin-chute common to all the first-named chutes, and a swinging hopper under the control of the operator for directing a coin from the coin-chute to any one of the first-named chutes, substantially as specified.

2. In a vending-machine, a series of compartments, a discharging device for each compartment adapted when released to discharge an article therefrom, a coin-receiving device for each discharger, a chute leading into each receiver, an electrically-operated device for releasing the discharger, a contact shovable in the receiver and having connection with said electric device, a chute extended from each receiver, a coin-chute having an opening at the front of the machine, and means under the control of the operator for directing a coin from said coin-chute into any one of the first-named chutes substantially as specified.

3. In a coin-controlled vending-machine, a receiver for a coin, having two communicating channels, contact and stop legs movable in said channels, contact-points adjacent to the receiver, and electrical connections closed by the coin for releasing a discharging device, substantially as specified.

4. In a coin-controlled vending-machine, a compartment or receptacle for goods, a discharging device for the goods, comprising a lever, means for moving said lever in discharging direction, an electromagnet carried by the lever, an armature carried by the lever and having swing-

ing connection therewith, a latch for engaging with a notch in the armature, and contact-points adapted to be closed by a coin for closing the circuit through the electromagnet, substantially as specified.

5. In a vending-machine, a series of compartments, a discharging device for each compartment, a coin-receiving device for each discharger, a chute leading into each receiver, a coin-chute having an opening at the front of the machine, and means under the control of the operator for directing a coin from said coin-chute into any one of the first-named chutes.

6. In a coin-controlled vending-machine, a series of receptacles for articles to be sold, the said receptacles being independent one of another, a coin-receiver for each receptacle, a discharging device for each receptacle, the said discharging device having an electromagnet for causing its release, the circuit through the magnet being closed by a coin in the receiver, chute leading to the receiver, a coin-chute, a hopper for receiving the coins from the coin-chute, a shaft on which said hopper is mounted, whereby it may be moved to discharge a coin into any of the first-named chutes, a crank on said shaft having a handle portion extended through an arc slot in the machine-casing, and a returning device for the shaft, substantially as specified.

7. In a coin-controlled vending-machine, a plurality of compartments or receptacles for articles to be sold, a discharging device for each receptacle, a shaft for each of the discharging devices, a coin-receiver for each of the receptacles, a leg mounted to slide in each receiver, the said leg being moved by connections with the shaft, draw-bar having connection with the shaft, the said draw-bar having hook ends, a bar on which the draw-bar slides and which is designed to be engaged by said hook ends, an upwardly-extended lever to which the bar is attached, and a push-rod for moving said bar in one direction, substantially as specified.

8. In a vending-machine, a series of compartments, a discharging device for each compartment, a coin-receiving device for each discharger, a chute leading into each receiver, a coin-chute having an opening at the front of the machine, a hopper for receiving the coins from the coin-chute, a shaft on which said hopper is mounted, whereby the hopper may be moved to discharge a coin into any one of the first-named chutes, and means for holding the shaft in the desired position, substantially as specified.

9. In a coin-controlled vending-machine, a compartment or receptacle for goods, a discharging device for the goods comprising a lever, a spring for moving the lever in the discharging direction, an electromagnet mounted on said lever, an armature, an arm carrying said armature and pivoted to the discharging-lever, means for engaging said arm to hold the discharging-lever in inactive position, a coin-receiver, and contact-points adapted to be engaged by a coin to close the circuit through the electromagnet, substantially as specified.

10. In a vending-machine, a plurality of receptacles for goods to be sold, a discharging-lever for each receptacle, a shaft for each of the discharging-levers and provided with an arm, a coin-receiver for each of the receptacles, a stop-leg for the coin mounted to slide in each receiver, connection between said stop-legs and the respective arms on the shafts of the levers, draw-bars connected with said arms and having hook ends,

a bar on which the draw-bars slide and adapted to be engaged by the hook ends, a lever to which the bar is attached, and a push-rod for moving said lever in one direction or out forth.

698,985. ELECTRIC CLOCK. EARL HYMAN, Jersey City, N. J., assignor of one-half to John M. A. Milligan, Jersey City, N. J. Filed July 15, 1901. Serial No. 62,955. (No model.)

Claim.—1. An electric clock having a pendulum, a pendulum-crutch provided with cross-arms, a weighted arm for striking one of the cross-arms to give an impulse to the pendulum in one direction, and an electrical device for raising the weighted arm, said electrical device comprising a circuit, an electromagnet in said circuit, a circuit-closer for said circuit and controlled by the other arm of the pendulum-crutch, and means connected with the armature-lever of the said electromagnet, for imparting an upward movement to said weighted arm when the pendulum-crutch closes the circuit, as set forth.

2. An electric clock having a weighted arm for imparting movement to the pendulum in one direction, an electrical device controlled by the pendulum and arranged to return the weighted arm to an inactive position, and a retaining device controlled from the pendulum, for temporarily holding the weighted arm in a raised position, said retaining device comprising a spring-pressed arm having a lag adapted to be engaged by the free end of said weighted arm, and means on said crutch for periodically imparting a swinging motion to said spring-pressed arm, to move the lag out of engagement with said weighted arm, as set forth.

3. In an electric clock, the combination with a pendulum crutch or fork provided with oppositely-arranged arms, of a pivoted and weighted arm adapted to strike one of the arms of the pendulum crutch or fork, a locking device for holding the weighted arm raised, means controlled by the crutch or fork for releasing the locking device to allow the weighted arm to fall, an electromagnet, means operated by the armature of the magnet for swinging the weighted arm upward into engagement with the locking device, and a circuit-closer controlled by the other arm of the pendulum crutch or fork, as set forth.

4. In an electric clock, the combination with a pendulum crutch or fork provided with oppositely-arranged arms, of a pivoted and weighted arm adapted to strike one arm of the pendulum crutch or fork, an electromagnet, a circuit-closer controlled by the other arm of the pendulum-crutch, a pivoted lever having one end connected with the armature of the electromagnet and its other end operatively connected with the weighted arm, a locking device for holding the weighted arm raised, and means for operating the locking device to release the weighted arm, as set forth.
